                                                                                                                                                                                                                                                                                                                                                                                                       |    

                                                                                                                                                                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                         | -                                                                                                                                                                                                                                                                                                                                                                                                         | -       ### for the Completion of Boiler Work Are Indicated

repairs come into the shop unexpectedly or unavoidable delays in the repair of parts occur, three or four locomotives on the regular schedule of the preceding month have to be carried over for completion on the revised current schedule.

The mechanical department as a rule provides for 30 to 35 light and general repairs a month, about 12 to 15 of which are firebox repairs, so that the foremen know approximately what will be required of them each month.

In order to promote production within the departments, a system of power trucking is employed by the routing department which keeps parts supplied wherever required without unnecessary delay.

### WORK OF THE BOILER DEPARTMENT

Boiler work is carried out whenever possible in the back shop. When heavy firebox repairs are necessary the boiler is brought into the boiler shop. As previously noted, the force in the boiler shop is also required to take care of a great many of the running repairs in the roundhouse. About 160 men are included in the staff of the boiler shop. A portion of the shop is devoted to sheet metal and tank work. The shop equipment is quite complete and arranged in a series of small departments, feeding the work on the assembly floor. The flue department is a unit by itself, while the layout department and the machine tool section are located so that there is no interference between them.

### FIREBOX REPAIR METHODS

It is the practice to carry out all but complete firebox repairs when an entire rear end is necessary with the boiler on the frame. Three or four sheet jobs are taken care of in the shop with the boilers still mounted. Half side sheets and lesser work can generally be handled in the back shop.

For half side sheet repairs, for example, the staybolts are burned out, the sheet cut and dropped. The new sheet is laid out from the old one which is used as a template. When the new sheet is ready and laid out with the edges to be welded double v'd it is bolted up and welded inside and

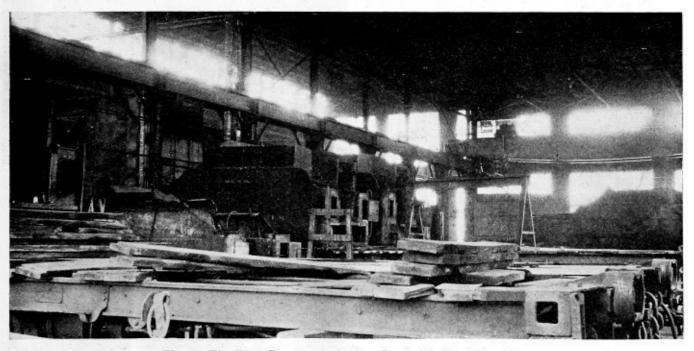

Fig. 4.-The Tank Department Is Also Located in the Boiler Shop

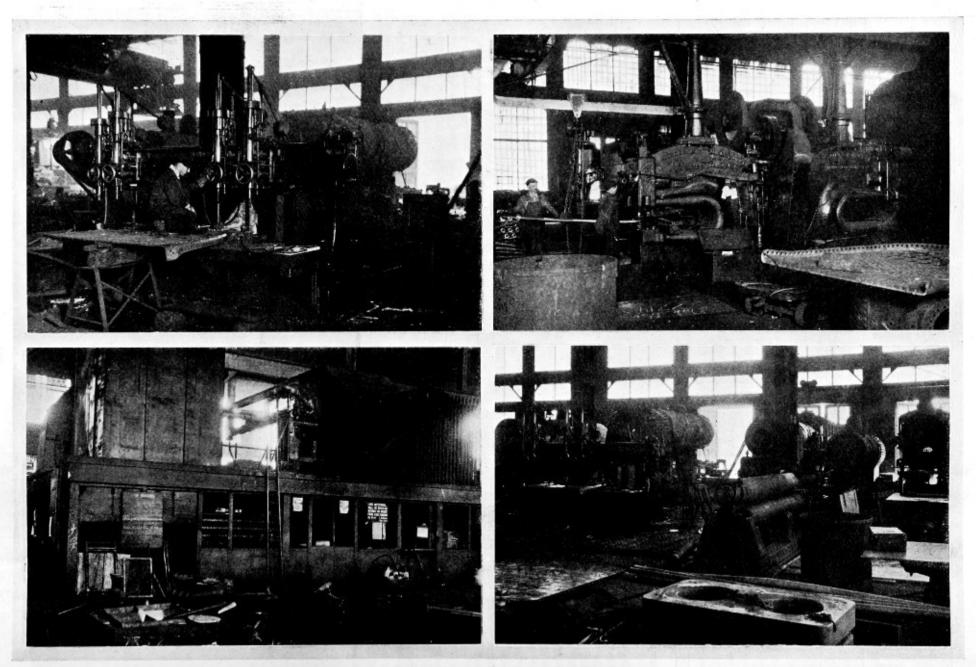

Fig. 4.—This 4 Spindle Gang Drill Saves Times in Sheet Drilling Operations. Fig. 5.—Powerful Punch and Shear Used in Sheet Fabrication. Fig. 6.—Combined Tool and Stock Room Is Conveniently Located. Fig. 7.—Heavy Machine Section Adjacent to Assembly Floor out wherever the parts are accessible. When the back head is renewed it is laid out from the old sheet, flanged, bolted in place and the flange holes marked out. The door hole in each case is butt welded. When a new firebox is fitted, the boiler is taken down from the frame, turned over and the firebox dropped into place.

A McCabe machine for cold flanging is installed and this takes care of practically all flange work except throat sheets. With the 11/16-inch and 34-inch sheets used in the throat it is necessary to do the flanging by hand.

Flue sheets are laid out from templates kept in stock for each class of engine coming into the shop. Holes are punched small and drilled out to size in the flat. Wherever possible, the work is laid out on the bench in the flat before flanging with the exception of the flange rivet holes which are drilled in position.

The edges of flanges are scarphed with the oxy-acetylene torch with a great degree of success. After the cutting operation the flange is chipped clean, the finished work having almost the appearance of machine scarphing.

### LACK OF UNIFORMITY IN BOILERS

In all this work it is found that there is a lack of uniformity in boilers of a given class that come in for repairs.

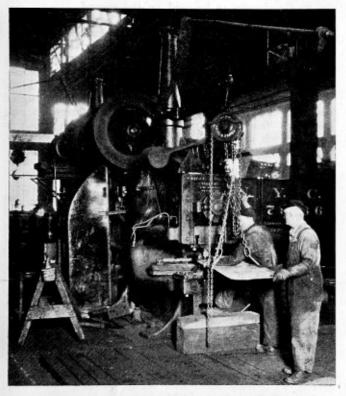

Fig. 8 .- Working on Sheets for the Tank Department

Even boilers made by the same builder vary somewhat. The discrepancies become apparent when the blue prints supplied with the locomotives when new are used to lay out sheets or heads. No doubt service conditions where the sheets are exposed to heat and weaving action on the road are responsible for the distortion and pulling out of shape. In any event better results are obtained in practically every case by using the discarded parts for fitting up new ones.

### RECONDITIONED FLUES

Small tubes are safe ended satisfactorily four or five times while superheater flues are safe ended twice only before they are reclaimed. Mandrels in connection with the welding hammers will take care of safe ends up to 34 inches in length. In the reclaiming process sections of tubes up to 8 feet or 9 feet in length are welded on. Practically all tube work for the Detroit shops and other Michigan Central shops in this section is done at Jackson so that it is necessary to keep two shifts running in the flue department at all times.

Two dry rattlers are installed at one end of the plant, each of which will take a charge of 275 small tubes and 40 to 50 superheater flues. Depending on the condition of the tubes and the water section from which they came the time for cleaning varies from 4 to 6 hours.

The safe end department has a capacity of about 120 small tubes an hour. The first part of the process consists in heating the flue, cutting and expanding it on a combination hot saw and expanding machine. After the end is trimmed it is belled on a tapered mandrel so that it will receive the safe end easily. The safe end is inserted on a pneumatic machine. The tube and safe end are then brought to a welding heat and inserted over the mandrel in the welding hammer. The welding hammer is of the half round type which has been found most satisfactory for insuring tight welds. The welded surfaces are finished on a fully round hammer after which they are cut to length. Each tube is tested under an air pressure of 130 pounds. In this test the regular shop air pressure of 110 pounds is used in conjunction with a booster which raises it to 130 pounds.

The tubes are installed with a sectional expander at the rear end while a special tool is used at the front end for expanding, at the same time. With this "double gunning" operation, it is unnecessary to hold on at the front end of the tube while the rear end is being worked. This procedure it can readily be understood saves considerable time in installing a set of tubes.

It is the practice to electric weld the superheater flues and the 2-inch intermediate tubes. Two and a quarterinch tubes and 2-inch tubes below the bank of superheater flues are not welded, however.

### CUTTING RECORDS MADE AT JACKSON

In the Jackson shops the cutting and welding operations incident to repair work are in charge of a welding foreman and a staff of exceptionally well trained operators. In fact oxy-acetylene cutting records have been established here by one of the operators that, as far as can be learned, have not been equaled in any shop in the country. An outline of these records will be of interest as a check against the work of the cutting departments in other shops.

Engine 7950 was brought into the shop for new side sheets and, as conditions seemed favorable for testing the speed of the operator who handles most of the boiler cutting work, a time record was kept for each of the dismantling operations. The total time taken for the work was 15 hours and 10 minutes and in this period 1,038 staybolts and 392 rivets were cut out and 24 feet of side sheet cutting completed.

On flange scarphing operations with the torch, this same operator completed a flue sheet flange and throat sheet in 1 hour and 10 minutes. The flue sheet flange alone without the throat sheet required 1 hour.

In cutting out superheater flues the operator burned off the beads of forty-three 53%-inch flues in 55 minutes.

At another time the front end netting, plates and petticoat pipe were removed in 45 minutes ready for flue removal.

One hour and a half was sufficient time to remove the sheet iron pan on a class G-6 freight engine. The cast iron pan on a K-3 passenger locomotive was removed in 1 hour.

In checking up the speed for cutting out staybolts the operator required only 1 hour and 6 minutes for 253 rigid staybolts in a G-6 freight engine. On another job 994 staybolts were cut in 2 hours and 10 minutes.

Incidentally the operator who set up these records is only 19 years of age. His training and experience were gained in the Jackson shops.

At a later time THE BOILER MAKER will publish further details of the welding and cutting work at Jackson.

# Trestles That Have Been Found Useful in Boiler Shops

Steel and Wood Trestles Made from Materials in the Shop to Meet Every Emergency-Kinks That Are Time Savers

By James F. Hobart

A GOOD trestle is a time-saver in any boiler shop and those concerns in which frequent use is made of boxes, barrels and cob-house timbering for supporting boiler and tank work may well afford to make up some steel trestles and save, by so doing, many hours now devoted to procuring and using wooden blocking.

Many a layout man would be glad of two or four rugged layout trestles as shown by Fig. 1, a trestle which will neither collapse nor tip over under any load likely to be placed upon it. This trestle is easily made up from material found in almost any boiler shop. The backbone A is a piece of stout structural T-steel. The feet or legs B and C may be fabricated from almost any half-inch plate, from tank steel to firebox stock, as may be available. The braces D and Eare pieces of angle structural steel and are fastened by rivets to the backbone and to the legs of the trestle. The slots in legs B and C may be made either by drilling, or punching and chipping, or by cutting with oxy-acetylene.

The writer saw this fine trestle in the Beech Grove shop of the "Big Four" railroad at Indianapolis, Ind., and the men in that shop did not seem at all particular as to the weight of boiler plate which they placed on a couple of these rugged trestles.

### ANOTHER NON-TIP TRESTLE

The trestle shown in Fig. 2 is almost as rugged as the one illustrated in Fig. 1. Originally made for use in boiler and machine shops, this heavy implement had been preempted by the wood working shop of the New Orleans and Lower Coast Railroad, and, when the writer saw it, was covered by a huge six-inch plank.

The backbone and legs of this trestle, as shown in Fig. 2, are made of heavy structural steel angles, six and four inches respectively. The legs sprawl out 45 degrees each, and from this the device takes its name, the pair of legs standing at 90 degrees, or "square" with each other. This construction makes it practically impossible to upset the trestle by sliding heavy steel or timber over it. The trestle is still further braced, endwise, by means of the sway-stays C, riveted to through-stay A, which in turn is fast to the legs at either end as shown at B. Brace C is also riveted to cross-brace D, which is located inside of the angle legs.

This form of construction makes a very strong trestle, capable of sustaining any load ever likely to be placed upon it, and, owing to the form of the top or backbone, it is especially adapted to use with heavy timbers and planks which can be pushed over the heavy angle with no danger of the timber catching a corner thereof, or of tipping over the trestle.

### LIGHT ANGLE-STEEL TRESTLE

A trestle of lighter construction also found in the New Orleans shop of the New Orleans and Lower Coast Railroad, has its angle steel backbone set upright as shown at A in Fig. 3. Both this angle and the legs C, C are riveted to a plate or clip B, which is made of pretty heavy steel. End-sway in this trestle is prevented by braces E, which are placed about the same as shown in Fig. 2, for the right angle trestle. The brace is fastened direct to clip B, also to through-stay D, which in turn is riveted to angle F on the lower portion of the legs. This trestle is of lighter con-

struction, yet strong and durable, but of course it will not stand as much hard work and abuse as the trestle shown in Fig. 2.

### PIPE TRESTLES

Three forms of all-pipe trestles found in the Beech Grove "Big Four" shops are shown in the following illustrations. One, a very light trestle, is quite portable and takes the place of the ordinary wooden "horse" as particularly affected by carpenters and machinists as well as boiler makers. It has, as shown in Fig. 4, a three-inch pipe E, for a backbone, with legs F, also through and cross braces made of inchand-a-half pipe. The round pad G, one under each of the four legs, prevents the pipes from sinking into the dirt when the trestle chances to be used on the ground.

Each and every joint in this trestle has been fitted and welded by the oxy-acetylene process, therefore there is not a rivet or a screw connection to be found, and the trestle is one of the smoothest and neatest bits of construction the writer has ever seen, without exception, in any boiler shop or anywhere else. While not designed for the heaviest kinds of hard work, this trestle, nevertheless, is mighty rugged and will stand up under a big load. The three-inch pipe used as a "back-bone" makes a handy place in which to keep a pinch bar or two, and the center-punch lives there, with a hammer handle thrust in, too, with the head protruding.

### ROLLER TRESTLE FOR BOILER TUBES

Another pipe trestle, but of much lighter construction and not designed to carry loads of much weight, is illustrated in Fig. 5. This trestle is also to be found in the Beech Grove shops, and it is intended to be placed alongside of the tube repairing machinery, merely to support one end of a boiler tube, while the other end of the tube is in the fire, or in a welding machine.

This trestle is also put together mostly by oxy-acetylene welding and is free also from rivets. It has the same clean and very neat appearance as is shown by the light pipe trestle described in a preceding paragraph. The backbone of this trestle consists of two pipes, one within the other, the inner and smaller pipe being welded to the ends of the trestle—they can hardly be called 'legs—the outer pipe serving as a loose roller over which the tubes pass when pushed into forge fire or welding machine.

Two screwed pipe connections are used in this trestle, one at either end of the pipe roller. The pipe upon which the roller revolves, is screwed into a steel elbow at either end, with just sufficient end-play for the roller between them. The other end of each elbow is fitted on a grinding wheel to bear fair against the top side of the curved end-pipes of the trestle to which the elbows are welded fast.

### A Welded-Pipe Ladder-Trestle

The very neat looking trestle shown in Fig. 6 is to be found in the Beech Grove shops. Alhough it was made in the boiler shop, I am sorry to have to admit that the boiler makers do not get much chance to use this type of trestle, which the car painting department preempted and which they hang on to, like taxes and interest to a home-builder!

This trestle is about the height stated, and has seven

### JULY, 1923

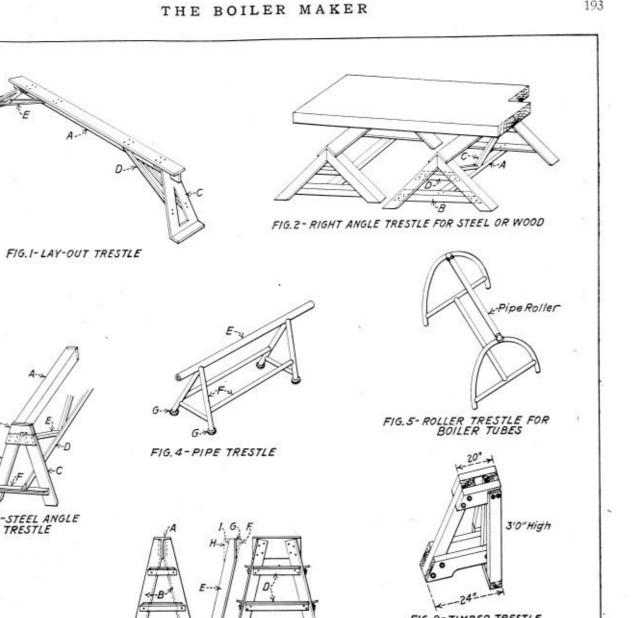

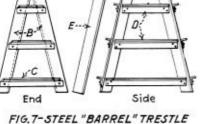

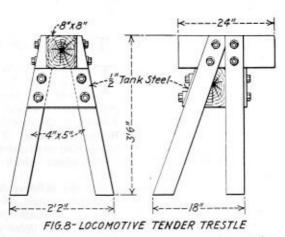

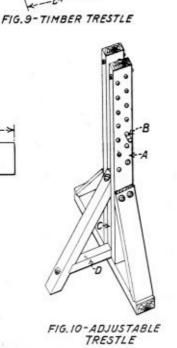

FIG.3

Types of Trestles Found in Use in Railroad Shops

193

steps or rungs on each of its four sides. The top measures 20 by 36 inches and the bottom, 48 by 54 inches. It is made of two-inch black pipe, the ends of each rung being fitted to the corner members and then welded fast thereto by the oxy-acetylene process.

Wooden ladder trestles of this kind are to be found in most car paint shops, a single plank being placed on top or on any convenient rung, the painters ascending to the planks by the convenient rungs on the sides of the trestle. Although, as stated, wooden trestles of this kind are common, metal ones are not usually found although "A" shaped trestles made entirely of small structural steel angles are in use in the West Springfield shops of the Boston and Albany railroad.

For lightness and stiffness, to say nothing of its pleasing appearance, the pipe trestle shown above is far beyond any other similar form of trestle which the writer has as yet come across.

### STEEL "BARREL" TRESTLES

Out in the Morris Park (N. Y.) shops of the Long Island Railroad, they used to keep stout barrels for placing underneath the front end of a boiler when it was to be propped up somewhere near level. They also used barrels for supporting other things during boiler repair and assembly into locomotives. But, as one of the officials remarked to the writer; "When barrels were used, the hoops *would* get loose, the barrels get rickety and then they would 'squat'!"

As a consequence, the very rugged little trestle illustrated in Fig. 7 was designed and it is needless perhaps to remark that never do these trestles "squat" under the heaviest load. The piece of T-steel A, which forms the top is twelve inches long. The bottom of the trestle is eighteen inches wide and twenty-four inches long. The height is the same as that of a barrel—thirty or thirty-two inches.

The legs B, B are of four-inch steel angle, the side rungs or braces are of lighter angle. Those on the ends C being placed on outside of the legs, while the side rungs D are placed between the flanges of the angles. The legs B were heated in a forge and bent, as shown by detail E, at F and G, until the web of the steel angle would lie flat against tee A. This action threw the side of the angle I into the position shown at H, but after the bending was completed the web at H was cut away until straight again as shown at I, thus permitting the leg flange to come flush with web of the T, as shown at A.

### WOODEN TRESTLES

Down in New Orleans, the "J. P. shops" are using stout wooden trestles under the front ends of locomotive tenders and elsewhere in boiler shop and tank work. One of these very rugged little trestles is shown in Fig. 8. Blocking is to be placed on top as required. They raise the tender from the truck, slip two rails under, upon four trestles, jack up the rails, block under them on the trestles, then run the tender truck out from under and remove the jacks thus completing the operation.

The dimensions and manner of construction are so plainly shown by the sketches that little description is necessary. Each shop may arrange minor details to suit the material at hand and the work to be done.

### LITTLE "JUMBO" TRESTLE

Another little wooden trestle which may be used for tender work, also for a great variety of other work in a boiler shop and elsewhere, is shown in Fig. 9. This trestle is made so it can be placed snug against a wall, all the bracing being sidewise and in front.

The dimensions of this trestle are shown in the illustration and its construction is very plainly shown. Only the size of the various timbers need be fixed in order to construct these trestles in your own shop, and the dimensions in question may be determined by the material at hand and the work which is to be handled by the trestle.

### Adjustable Side Trestle

Another timber trestle is shown in Fig. 10. By means of holes in the extended vertical members A, pin B may be inserted at any desired height to support a timber upon which a tender, a car-body, or some part of a locomotive boiler may require to be supported at a certain height.

The manner of construction is plainly shown, as is the excellence of the side bracing. It should be kept well in mind that the strength of this trestle depends largely upon the insertion of timber C between the two vertical timbers A and immediately above and resting upon timber D, to which, and to all the other timbers, C and A are most securely fastened.

# United States Civil Service Examination for Boiler Inspector

THE United States Civil Service Commission announces the following open competitive examination for local and assistant inspector of boilers.

The examinations will be held throughout the country on July 25 and 26. They are to fill vacancies in the Steamboat-Inspection Service, at entrance salaries ranging from \$2,100 to \$2,950 a year, and in positions requiring similar qualifications. Appointees at an annual compensation of \$2,500 a year or less may also be allowed the increase of \$20 a month granted by Congress.

For the position of local inspector of boilers, applicants must have had at least three years' experience as chief engineer of ocean or inland steamers of American registry of over 100 gross tons, or as first assistant engineer of steamers of American registry of 600 gross tons or over.

For the position of local inspector of hulls, applicants must have had at least three years' experience, under United States license, as master of seagoing steam vessels or of inspected seagoing motor vessels of American registry of over 100 gross tons, or in lieu of this experience they must have had certain other specified training and experience.

Applicants for the positions of assistant inspector of boilers and assistant inspector of hulls, must have had the same qualifications as those required for local inspectors, except that the required term of service is two years.

Full information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or the secretary of the board of U. S. civil service examiners of the post office or custom house in any city of the country.

# Training of Oxy-Acetylene Welders

THE American Welding Society has issued an outline of a course for the training of oxy-acetylene welders. This report was prepared by a committee and combines the experience of experts of the Federal Board of Vocational Education, the American Welding Society and the National Research Council. For the information of the person who is selecting candidates, the text includes a discussion of the qualifications which the candidates for training should possess.

For the information of the instructor, the text includes the fundamentals in gas welding, together with a detailed statement of content, classified under type welding jobs arranged in the order of difficulty. Copies may be secured from the American Welding Society, 29 West 39th street, New York.

# Cost Accounting

# Report Read at Annual Meeting of American Boiler Manufacturers' Association at Hot Springs, Va.

A^T the annual meeting of the association held in French Lick Springs in 1920 a report was presented and subsequently printed in pamphlet form which it was hoped would help those who wished to start some kind of cost accounting system in their own plant.

The following are some advantages to be derived from a cost system as pointed out by the fabricated production department of the Chamber of Commerce of the United States in their bulletin No. 22:

 Strengthens the position of the industry in dealing with governmental or regulatory bodies.

(2) Inspires confidence that selling prices are determined upon a fair and equitable basis.

(3) Solves disputed points of accounting within the industry authoritatively.

(4) Makes possible a more intelligent competition,(5) Reveals lines within the industry which have been mar-

(5) Reveals lines within the industry which have been marketed on an unprofitable basis.
 (6) Shows the danger line below which goods cannot be sold

(7) Acts as a common guide to the value, efficiency and waste

of workers, machines, methods, operations and plants.

(8) Becomes a reliable guide and basis for estimating prospective business, thus acting as a forerunner for comprehensive production statistics.

(9) Furnishes current rates for comparing major cost items with standards which are pre-determined and thereby measuring and increasing operating efficiency.

(10) Establishes a standard code of accounting practice so that if your cost clerk or bookkeeper leaves you his successor will step into a system whose operation has been fully and completely formulated.

Every manufacturer should have in his plant an accounting system so that every month he will know how much money he has made or lost, as the case may be, and know why the results as shown by the monthly statement are as indicated.

The cost of a boiler, stack, flues, tank, etc., is made up of three principal items:

(1) Material constituting same.

(2) Labor directly expended to fabricate it.

(3) Overhead.

(1) The material constituting the finished product ought to be called "direct material" inasmuch as material will go directly into the product as plates, tubes, etc. This is different from "indirect material" such as coal which goes to make up the overhead. The material that is purchased as "direct material" usually can best be handled by putting it into stock whether or not it is purchased for stock or actually for a particular product.

After an order has been received a bill of material should be made out; that is, a complete list of all material that is required to fill the order or manufacture the product; then requisitions or orders should be made out for all this material which is to be taken from stock or, if it is not in stock, ordered and put into stock; then when the requisitions that have been made out from the bill of material are filled the stock clerk sends them to the cost clerk who enters them on the cost. In this way no material can go into making up a product that does not appear on the cost.

If, for example, the bill of material is made up and by error some items are left out, they cannot go into the boiler until a requisition has been made out; then the cost clerk charges them to the job. In the above way of handling "direct material" little chance of error occurs and it tends to make up accurate costs. (2) Direct labor is the labor expended by the employees fabricating the article. There are a number of ways in which this is handled. One of the simplest, however, is to give each man a number. If he works say from 7 to 12 on job No. 2,000 he turns in his time card with his number on it and the nature of the work he performs. He gets another time card if he goes on to another job and turns his time in in a similar way; that is, he obtains from the time clerk or his foreman a new time card for every job he goes on to.

As to his rate, it is more simple to have an average rate in each department; that is, in the boiler shop, for example, there will be men whose wages vary say from 35 to 75 cents an hour and the average can be figured out at say 60 cents an hour; that is, every man's time is charged at 60 cents regardless of what he is actually paid. Careful check should be made to be sure that the time cards are properly issued and filled out. In this way the actual cost of labor on an article is obtained and what the different operations actually cost. So if the labor on a certain cost appears to be higher or lower than might be expected, it can readily be traced down and the reason for the discrepancy determined.

(3) Overhead is probably the most difficult part of the cost to have accurately and properly proportioned. Overhead should be made up of two principal divisions, namely: Shop overhead and administrative and selling overhead.

The reason why it should be divided is:

(1) According to the Federal laws, in making returns to the Government the work in process at the end of the year should appear as to its value based on material, labor and shop overhead. The same applies to material made up for stock; that is, not for firm orders. Shop overhead is made up of such items as:

Electric power. Repairs to buildings. Repairs to machinery. Insurance. Taxes on real estate and buildings. Fuel. Firm's time, etc.

A budget of this should be made up for the year; that is, an estimate as to what it should be. With past records this can be pretty accurately determined.

Suppose we take a hypothetical case and assume the shop overhead amounts to \$48,000 a year and that the plant will run at a fair average rate of productive hours—say 80,000 productive hours a year; then the shop overhead would be  $48,000 \div 80,000$  to determine the overhead rate per hour divide the shop overhead (48,000) by the productive hours (80,000) which gives 60 cents. It is better to have this cost appear with an overhead rate at 60 cents an hour than say 100 percent as your shop rate may vary and your overhead not vary.

If it is found, say after the first three months, that 60 cents is not the proper rate to take care of the overhead, or is too much, for the next three months it could be changed but, after the cost system has been in operation for some time and with accurate records available it can be pretty accurately determined. Shop overhead should appear on the cost monthly, as the work progresses, based on the productive hours expended.

(Continued on page 214)

# Layout of a Twisted Pipe

Method of Obtaining True Lengths, Correct Angle and Miter Line of Elbow

### By George A. Jones

TWISTED pipe work is very often encountered in connection with blast furnace work. To obtain patterns for this work, proceed with the center lines for the plan.

First draw the circle about O as a center equal to the outside diameter of the vertical pipe. Locate the centerline N-R- $N^x$  in the proper location and locate the centerline of the upright pipe N- $P^x$ .

#### ELEVATION

Above the plan erect centerlines for the elevation. First erect the vertical line from R, the point where the center line of the branch intersects the vertical cylinder and locate T. Then erect the vertical line through the center of the elbow N and locate  $E^i$  and E. Now erect the vertical line  $P^x - L$  and draw the center lines T-E and E-L. After the center lines are located draw the outlines of both pipes in the plan and elevation.

So far the pipe No. 1 is not shown in its true length or the angle of the elbow in its true angle, so more views will be necessary.

To lay out Fig. 5, at right angles to the center line N-R- $N^{x}$  of the plan erect the line N-A-B, then line R- $G^{*}$  and line  $N^{x}4$ . At right angles to line R-G draw line G-B and make the distance B-A equal to the vertical height E-E of the elevation. Now draw the center line A-G-4, Fig. 5. The distance A-G is the true length between these two points.

#### OUTLINES OF THE PIPE

Next draw the outlines of the pipe. Any place on the center line A-G-4 about the point S draw the semi-circle and the line I-S-7 at right angles to the center line. Divide the semi-circle into six equal spaces and number from I to 7. Draw lines through these points I to 7 and parallel to the center line A-G-4 of indefinite length towards 4. Now draw the semi-circle about point  $N^x$  of the plan and space 6 equal spaces. Through these points draw lines parallel to the center line N-R-N^x to the large circle, O, and locate the points 2 and 6, 5 and 3,  $6^x$  and  $2^x$ ,  $5^x$  and  $3^x$  and  $4^x$ . Lines dropped from these points at right angles to N-R-N^x to similar points in Fig. 5 will locate proper points on which to lay out the pattern for the branch end.

NOTE: When looking at Fig. 5, points on the near side are numbered I to 7 and on the far side  $2^{x}$ ,  $3^{x}$ ,  $4^{x}$ ,  $5^{x}$ ,  $6^{x}$ .

This completes Fig. 5. Now in the elevation extend the center line E-L on the bottom and at right angles to L-E and through T locate point K. Extend the center line L-E on top and locate  $F^i$  and draw the circle about  $F^1$ . Now return to the plan, extend the center line N- $P^x$  and locate point P.

Note: The end of the pipe P is shown by a straight line. This should be an ellipse but, as no measurements are taken from this view, it is not necessary to draw the ellipse.

#### Correct End View

Now draw the line R- $R^{1}$  parallel with the center line N- $P^{x}$ -P and line P- $R^{1}$  at right angles to P-N. The distance P- $R^{1}$  that the pipes are off center in the plan is transferred to the center line E-L of the elevation and F- $F^{1}$  is located. Next draw line F-H at right angles to the center line. Now draw line H- $F^{1}$ . As this is a correct end view, the line  $F^{1}$ -H shows the direction of the center line of pipe

No. 1. As the direction is from  $F^{1}$ -H, where this line crosses the circle locates the back of the elbow as 7, and the throat of the elbow as I. Space the circle  $F^{*}$  the same as circle  $N^{x}$  of the plan. Number the points on the near side I to 7 and those on the far side  $2^{x}$ ,  $3^{x}$ ,  $4^{x}$ ,  $5^{x}$ ,  $6^{x}$ .

In the plan make  $R^1$ - $S^1$  equal K-T of the elevation and draw line P- $S^1$ . This line represents the direction of pipe No. 1 in this view. Just as line  $F^1$ -H in the elevation where line P- $S^1$  crosses the circle point No. I is the throat and point 7 the back of the elbow and center line P- $S^1$  of the plan should equal center line  $F^1$ -H of the elevation.

### Correct View of Miter Line

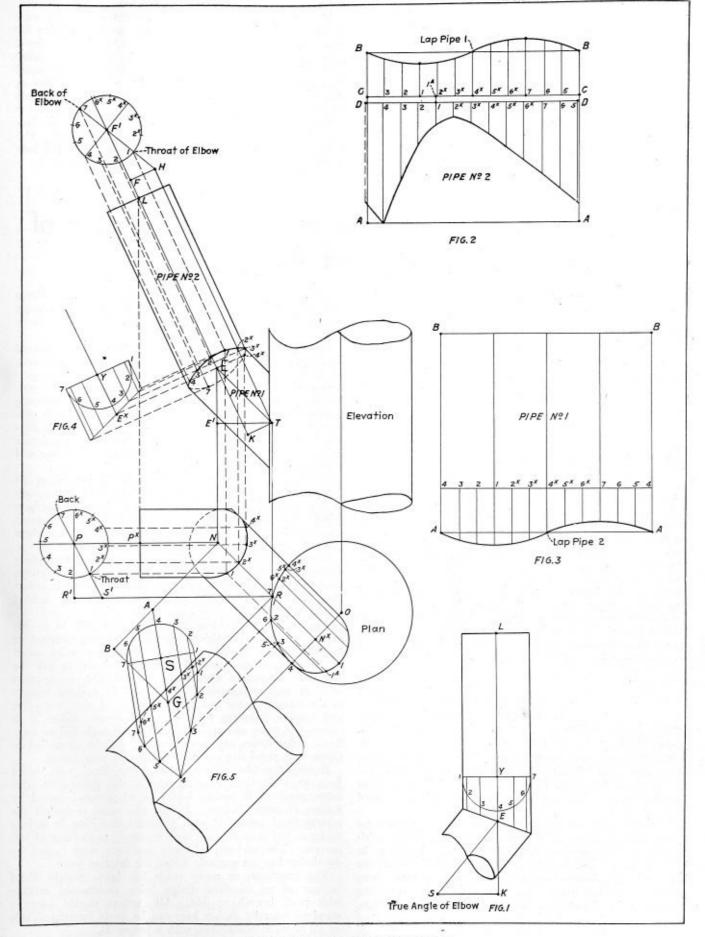

As the center line E-T of the elevation and N-R of the plan are foreshortened and not shown in their true length, it is necessary to erect a correct view of the miter line of the elbow at E of the elevation and N of the plan showing the miter line in a true position. To do so, first obtain a true angle of the elbow, as shown at Fig. 1. Erect the center line L-K, Fig. 1, equal to L-K of the elevation. Make L-E, Fig. 1, equal L-E of the elevation, which is shown in its true length. Now draw K-S, Fig. 1, at right angles to L-K and make K-S equal  $F^{1}$ -H of the elevation or P- $S^{1}$  of the plan and draw the line E-S. Now the angle L-E-S is a correct angle of the elbow and these are the true lengths. E-S should equal A-G, Fig. 5, also, which is also the correct length.

On the line  $\overline{L}$ - $\overline{E}$ , Fig. 1, at Y draw a semi-circle, space this the same as circle S or  $N^x$  and draw lines to the miter line. Parallel with the center line L- $\overline{E}$  of the elevation draw the line Y- $E^x$ , Fig. 4. Transfer the section at Fig. 1 to Fig. 4, as shown, the line E- $E^x$  being at right angles to L- $\overline{E}$ . Lines drawn over from the miter line in Fig. 4 to E of the elevation parallel with E- $E^x$  intersecting similar numbered lines drawn from the circle  $F^i$  and parallel with the center line L-E will locate the points around E showing a true view of the miter line of the elbow and numbered 7, 4, 3, 2, 1,  $2^x$ ,  $3^x$ ,  $4^x$ . All lines have not been drawn in order not to confuse the reader but it will be easily understood. The section of the miter line on the near side is drawn with a full line and on the far side with a dotted line.

## ELBOW MITER LINE IN THE PLAN

As pipe No. 1 of the elevation is foreshortened, we must locate the elbow miter line in the plan. To do so, space the circle P of the plan the same number of spaces as circle  $F^1$ of the elevation. Number the points on the near side I to 7 and those on the far side  $2^x$  to  $6^x$ . Through these points and parallel with the center line  $P-P^x-N$  run lines to N and drop vertical lines down from E of the elevation to similar numbered lines at N. Where they meet draw the ellipse as shown. This is a correct view of the miter line of the elbow. All lines have not been drawn but enough to show the method and marked I,  $2^x$ ,  $3^x$ ,  $4^x$ .

As the plan or outline shown about  $N-R-N^x$  is a correct end view for Fig. 5, and as point *I* on the ellipse at *N* is the correct location of the throat of the elbow, run line through *I* and parallel with center line  $N-R-N^x$  to the semicircle  $N^x$  and locate point  $I^a$  on this circle. The distance measured from *I* to  $I^a$  on the circle is the twist that the point *I* for the elbow layout is set to the left of point *I* for the branch layout. Readers will notice that drawing all the

Details of Twisted Pipe Development

197

ellipse at E of the elevation and N of the plan is not necessary; as will be seen, only the point I or throat has been used. But it is necessary to understand the method of obtaining the ellipse in order to understand the work when just the point I is used.

### PATTERNS

The pattern for pipe No. 1 is shown at Fig. 3. The lengths are obtained from Fig. 1. Turn over to roll. In Fig. 2, erect line A-A, the circumference, square up the plate and erect lines A-B equal to A-4 of Fig. 5 and draw line B-B from B on line B-A. Locate point C equal to E-Y, Fig. 1, and draw line C-C. Space this line and develop this

end for the elbow exactly the same as regular elbow work. Make the distance A-D, Fig. 2, equal S-4, the long point of the branch, Fig. 5, and draw the line D-D. With the distance I to  $I^{a}$  on the semi-circle  $N^{x}$  of the plan transfer it to the right of point I on line C-C of Fig. 2, and locate point  $I^{a}$  for the branch; drop this to line D-D. Space off equal spaces both sides of point I. On line D-D erect lines as shown and obtain the lengths for these same lines from Fig. 5.

The curve drawn through these points completes the layout. Allow for laps and flange and turn over to roll. The dotted portion on the left of the pattern is cut off. The hole in the cylinder is obtained from the branch and Fig. 5.

# Papers and Reports Read at 1923 Convention of Master Boiler Makers

SPACE did not permit the publication in the June issue of THE BOILER MAKER of all the papers and reports read at the Master Boiler Makers' convention held at Hotel Tuller, Detroit, May 23 to 26, so those that were omitted at that time are given below.

# Review of Locomotive Accidents During the Year

### By J. A. Shirley*

A S you know, the purpose of the locomotive inspection law is to promote the safety of employes and travelers by compelling common carriers engaged in interstate commerce to equip their locomotives with safe and suitable boilers and appurtenances thereto.

The law was amended March 4, 1915, to include the entire locomotive and tender. Since the law was enacted and the rules and regulations promulgated thereunder, which became effective July 1, 1911, there have been reported to the Interstate Commerce Commission up to March 31 of this year 8,259 accidents resulting in the death of 582 persons and the serious injury of 9,324 others, due to the failure of some part or appurtenance of the locomotive or tender.

Compare the number of accidents, number killed, and number injured, as a result of the failure of some part or appurtenance of the locomotive boiler to which the original act applied only.

		Year end	led June	30	nine of year	irst months fiscal r ended ne 30
	1912	1915	1921	1922	1922	1923
Number of accidents Number killed Number injured	826 91 1,005	424 13 467	342 51 379	273 25 318	214 20 253	398 37 471

You will note that accidents increased 86 percent, killed 85 percent, and injured 86 percent, during the first nine months of our fiscal year 1923, which began July 1, 1922, as compared with a like period during the fiscal year ended June 30, 1922.

It is to be regretted that some carriers appear to consider a congestion of traffic or an unfavorable condition a legitimate excuse for operating locomotives that are known to be in an improper condition for service and in violation of the law until the locomotives are found and ordered from service by our inspectors. The responsibility for operating locomotives in violation of the law rests upon the carriers,

* Mr. Shirley represented A. G. Pack, Chief Inspector of the Bureau of Locomotive Inspection.

yet we have been compelled to bring court proceedings against a number of the carriers for infliction of the penalty provided by law, in order to bring about a compliance therewith.

Investigation of accidents where the fusion or autogenous welding process was involved supports our position previously taken that the process has not yet reached a state of perfection where it can be safely depended upon in boiler construction and repair, where the strain to which the structure is subjected is not carried by other construction which conforms to the requirements of the law and rules, nor in firebox crown sheet seams where overheating and failure are liable to occur, nor its excessive use in repairing long and numerous cracks in side sheets.

Our records show that approximately 77 percent of all autogenously welded seams involved in so-called crown sheet failures have failed, while 15.9 percent of riveted seams have failed under like conditions. The fatalities where sheets tore have been seven and one-half times as great as where they did not tear.

From July 1, 1906, to March 31, 1923, autogenously welded seams were involved in 24.3 percent of the crown sheet failures, while 46.5 percent of the total killed in crown sheet accidents were killed where the autogenously welded seams were involved.

The autogenous welding process is practically in its infancy and due to our desire to avoid hindering progress or the development of any process of such great value when properly and discreetly used we have hesitated to ask the Interstate Commerce Commission to establish or approve rules or regulations restricting its use in making repairs to the various parts and appurtenances of the locomotive and tender, including the boiler. However, unless it is confined to parts and appliances where through failure accidents and injuries will not result, we will be compelled to adopt some restrictive measures in the very near future.

During the first nine months of the fiscal year ended June 30, 1922, there were reported to this Bureau 39 accidents, resulting in serious injury to 39 persons, caused by failure of grate shakers. During the same period of the present fiscal year, 102 such accidents, resulting in serious injury to 102 persons, have been reported; an increase of 160 percent. The majority of these accidents were caused by the shaker bar not properly fitting the fulcrum lever.

This condition on many roads has been brought about because of no standard design being maintained making such parts interchangeable. All carriers should adopt a standard whereby shaker bars can be made interchangeable on all of their locomotives, with a proper fit.

199

The chance-taker is still with us. There has been a great increase in the number of accidents caused by attempting to tighten washout plugs while there is pressure in the boiler. No doubt some of the persons killed or injured in these accidents did not realize the danger to which they exposed themselves and others, but the foreman most assuredly did; he should see that employes are not exposed to needless danger from that source by absolutely prohibiting attempts to tighten washout plugs while the boiler is under pressure.

# The Use of Automatic Stokers in Locomotives

THE effect of automatic stokers on firebox sheets is dependent upon the efficient operation of the stoker. If the stoker spreads the fuel over the entire grate surface evenly and the admission of air under the fire is such as to insure proper combustion, and the stoker is operated so that the opening of fire door is reduced to a minimum, the firebox sheets are benefited, and the checking and cracking of plates due to admission of cold air to the hot plates, is reduced.

The admission of enough air, properly distributed through the ashpan is essential to proper combustion, and has a great deal to do with the efficient operation of the stoker. If enough air is not admitted, or is admitted at the wrong point, it tends to make an uneven fire, and consequently an uneven heat on firebox sheets, which tends to check and crack them.

On a hand fired locomotive, the fireman is continually feeding fuel to the low spots on his fire, and if the air admission or draft is such as to burn his fire bright in spots he overcomes the tendency of an uneven fire by adding fuel to the places that need it. The stoker is designed to spread the fuel evenly over the grate surface and if combustion is poor in spots the stoker, if not watched closely, will aggravate this condition by a continued piling on of more fuel which is not consumed. Quality of fuel also enters largely into the efficient operation of the stoker.

From reports covering the hand fired vs. stoker fired locomotives, it has been noted that the temperature of the firebox dropped from 100 to 200 degrees when the fire door was opened for a sufficient time to apply fuel. In one case the pyrometer was put through a hole in the side sheet and registered the temperature of the air along the side of the firebox, but did not represent the temperature of the air directly above the fire door or on the crown sheet, which no doubt would be dropped to a greater degree.

When air at atmospheric temperature is admitted to the firebox, it must be heated to the igniting degree and if it enters in large volume through the firebox door, it makes it possible to flash through the firebox against the flues and side sheets before ignition temperature is reached, causing a contraction of the metal which is detrimental to both flues and firebox sheets, as well as combustion. We therefore feel that on the stoker fired engine efficiently operated, the fire door can be kept closed and that exclusion of cold air entering above the fire can be reduced, and the life of the firebox and flues lengthened on account of the air being properly heated as it rises through the fuel bed, creating better combustion and maintaining an even temperature throughout the firebox.

We have been unable to gather any authentic comparative data on the cracking of firebox sheets in stoker fired vs. hand fired locomotives. From reports from several roads where the stokers have been in use five years or more it is the consensus of opinion that the firebox sheets do not crack as readily on a stoker fired engine as on a hand fired engine. One road reports that with the same class of power in the same district no difference is noted. We would therefore refer this portion of the topic to the convention for discussion.

This report was prepared by a committee consisting of H. A. Bell, chairman; C. A. Nicholson and C. J. Baumann.

# Efficiency of Combustion Chamber Boilers

WING to the importance of the subject your committee sent inquiries to those members who have had the longest experience with the chamber.

The inquiries included: "General efficiency of chamber. Defects that were first to develop and remedies applied. Number of broken bolts per engine per month, and kind of bolt. Defects developing in the various parts of the chamber, and the life of the parts. Size or length of chamber. The diameter, length and number of tubes and flues. Whether equipped with brick arch or not. Hand fired or stoker? If chambers were not a success what was done to make them so?

We were much surprised and gratified with the prompt and full replies received, and the uniform desire shown to help the committee and Association as much as possible. We desire to thank these members for their assistance, and congratulate the Association on having these men as members.

There is a remarkable difference in the efficiency and life of the chamber on the various railroads using them. Some railroads are equipping old power with the chamber, others are removing the chamber and applying the straight box, also ordering new equipment with the straight box. There also is a great difference in the length of chambers: Those mentioned in our correspondence are 24, 29, 30, 36, 42 and 56 inch.

The majority of writers agree on the fact that the chamber is the cause of breaking many more staybolts than were broken in the straight box. Although most of this has been taken care of by the application of flexible bolts, one writer says: "We renewed as many as 35 to 40 staybolts per engine per month, and although we applied a full installation of flexible bolts, we still find many broken bolts."

Another member wrote: "Since applying a full installation of flexible bolts we have very little trouble with broken bolts."

Other defects that develop are cracks at rivet holes of circular seam and wings of throat sheet, the former sometimes extending into the base of flange.

Pits, grooves and cracks, occur along both top and bottom base of flue sheet flange and from base of flange to flue holes. These cracks often extend in both a vertical and horizontal direction, sometimes extending through bridges. Cracks at arch tube holes. Cracks at front row of staybolt

holes in bottom of chamber extending from 18 to 30 inches in length. Cracks at base of throat sheet wings. Excessive pitting and grooving of wrapper sheet back of

flue sheet seam and over front portion of crown.

And staybolt leakage in bottom of chamber.

To remedy the trouble with circular seams and wings flanges and wings of new throat sheets were extended and autogenously welded.

Defective flue sheets were renewed in some cases at the end of two years' service; in other cases at the end of three or four years. One member wrote: "Back flue sheets in our Pacific type engines with 72 inch shell and 36 inch combustion chamber last seven years. With straight standard firebox flue sheet gave four years' service." Two other members wrote: "Our combustion chambers are seven years old, but we have not renewed any flue sheets." The tendency to crack at arch tube holes was taken care of by one member by additional bracing when renewing throat sheet. The cracks at base of throat sheet wings were remedied by increasing the radius of the flange in new applications. The leakage of bolts in bottom of chamber was stopped by applying a layer of fire brick over the affected part.

A majority of the writers agreed that the tubes and flues were more efficient in the chamber type boiler, and their mileage was increased from 50 to 100 percent.

There is considerable difference in the number and length of tubes and flues in the combustion chamber boilers. The smallest has 158, 2-inch and 22,  $5\frac{1}{2}$ -inch, length 16-feet 2 inches; the largest has 275  $2\frac{1}{4}$ -inch and 50,  $5\frac{1}{2}$ -inch, length 21 feet 0-inches.

Basing our judgment on personal experience and on the experience of other members who have had a great deal of trouble with a large number of combustion chamber boilers we have concluded that, "The new combustion chamber boilers are not as easy to maintain as the straight standard firebox."

The chairman wishes to thank Mr. Ziegenbein for his very prompt and efficient assistance as a member of the committee.

# Rules Governing the Care of Stationary Boilers

1. Safety Valves: Great care should be exercised to see that these valves are ample in size and in working order. Overloading or neglect frequently lead to the most disastrous results. Safety valves should be tried at least once every day to see that they will act freely.

 Pressure Gage: The steam gage should stand at zero when pressure is off, and it should show the same pressure as the safety valves when that is blowing off; if not, then one is wrong, and the gage should be tested by one known to be correct.

3. Water Level: The first duty of an engineer before starting, or at the beginning of his watch, is to see that the water is at the proper height. Do not rely on glass gages, floats or water alarms, but try the gage cocks. If they do not agree with water gage, learn the cause and correct it. Water level in Babcock & Wilcox boilers should be at center of drum, which is usually at middle gage. It should not be carried above.

 Gage Cocks and Water Gages: Must be kept clean. Water gage should be blown out frequently, and the glasses and passages to gage kept clean.

5. Feed Pump or Injector: These should be kept in perfect order, and be of ample size. No make of pump can be expected to be continuously reliable without regular and careful attention. It is always safe to have two means of feeding a boiler. Check valves and self-acting feed valves should be frequently examined and cleaned. Satisfy yourself frequently that the valve is acting when the feed pump is at work.

6. Low Water: In case of low water, immediately cover fire with ashes (wet if possible) or any earth that may be at hand. If nothing else is handy use fresh coal. Draw fire as soon as it can be done without increasing the heat. Neither turn on the feed, start or stop engine, nor lift safety valve until fires are out, and boiler cooled down.

 Blisters and Cracks: These are liable to occur in the best plate iron. When first indication appears there must be no delay in having it carefully examined and properly cared for.

8. Fusible Plugs: When used, must be examined when boiler is cleaned, and carefully scraped clean on both the water and fire sides, or they are liable not to act.

9. Firing: Fire evenly and regularly, a little at a time. Moderate thick fires are most economical, but thin firing must be used where the draught is poor. Take care to keep grates evenly covered, and allow no air holes in fire. Do not "clean" fires oftener than necessary.

 Cleaning: All heating surfaces must be kept clean outside and in, or there will be a serious waste of fuel. The frequency of cleaning will depend on the nature of fuel and water. As a rule, never allow over 1/16-inch scale or soot to collect on surfaces between cleanings. Handholes should be frequently removed and surfaces examined, particularly in case of a new boiler, until proper intervals have been established by experience.

The Babcock & Wilcox boiler is provided with extra facilities for cleaning. For inspection and washing, remove handholes at both ends of tubes, and by holding a lamp at one end and looking in at the other, the condition of the surface can be fully seen. Run the Rotary flue cleaner through the tube until it is clean and free from sediment. In replacing hand-hole caps, clean surfaces without scratching or bruising, smear with oil, and screw up tight. Examine mud-drum and remove sediment therefrom.

The exterior of tubes can be kept clean by the use of blowing pipe and hose through openings provided for that purpose, and must be given frequent attention. In using smoky fuel, it is best to occasionally brush the surfaces when steam is off.

11. Hot Feed-Water: Cold water should never be fed into any boiler when it can be avoided, but when necessary it should be caused to mix with the heated water before coming in contact with any portion of the boiler.

12. Foaming: When foaming occurs in a boiler, checking the outflow of steam will usually stop it. If caused by dirty water, blowing down and pumping up will generally cure it. In cases of violent foaming, check the draft and fires.

13. Air Leaks: Be sure that all openings for admission of air to boiler and flues, except through fire, are carefully stopped. This is frequently an unsuspected cause of serious waste.

14. Blowing Off: If feed water is muddy or salt, blow off a portion frequently, according to condition of water. Empty the boiler every week or two, and fill up afresh. When surface blow-off cocks are used, they should be often opened for a few minutes at a time. Make sure no water is escaping from the blow-off cock when it is supposed to be closed. Blow-off cocks and check valves should be examined every time the boiler is cleaned.

 Leaks: When leaks are discovered, they should be repaired as soon as possible.

Blowing Off: Never empty the boiler while brickwork is hot.

 Dampness: Take care that no water comes in contact with exterior of the boiler from any cause, as it tends to corrode and weaken the boiler. Beware of all dampness in seatings or coverings.

This report was prepared by a committee consisting of J. J. Davey, chairman; Charles Zeitz and George C. Nicol.

### **Topics for 1924 Convention**

EREWITH is a list of subjects recommended for the 1924 convention:

No. 1. Most economical method of cutting off and removing mudring rivets, and cost.

No. 2. The training and developing of apprentices.

No. 3. Does the application of thermic syphons increase the life of firebox sheets and flues?

No. 4. Most economical method of removing firebox sheets for renewal, describing method and cost. Is it more economical to renew firebox without removing boiler from the frame?

No. 5. Increased output per man hours.

No. 6. Shop kinks.

Additional topics will be published later.

The chairman of the Committee on Topics was John F. Raps.

# Diameters and Heights of Stacks for Steam Boilers*

### By E. C. Fisher†

The need for more rational, more practical formulæ for determining the size of chimneys for steam boilers has for some time been recognized. The real need, however, has recently been forcefully brought to the attention of boiler and stoker manufacturers because of the high ratings now being demanded. These high ratings are accompanied with high draft loss through the boilers, due to increased volumehence velocity-of the gases, which in turn greatly increase friction. This loss has naturally rendered present chimney tables obsolete.

DECAUSE of the importance and general interest of this B problem our President placed it before the joint committee of this Association and the Stoker Manufacturers' Association for solution if possible. The joint committee met and made a study of the problem. They realized that proportioning chimneys and breechings from grate area was illogical and that the rational method was to work from a gas basis where volume and the velocity are taken into consideration. There was considered in this study the paper of Mr. A. L. Menzin, entitled "Proportioning Chimneys on a Gas Basis," presented before the American Society of Mechanical Engineers at the annual meeting, December, 1915, and to be found in the Transactions, Vol. 23, page 1065. The committee recommends the reading and study of that paper because the theory here used is very clearly and simply set forth in that paper.

The paper entitled "Charts for Determining Stack Di-mensions," by Mr. R. A. Foresman, chief engineer of the Stoker Department of the Westinghouse Electric and Manufacturing Company, printed in Power, November 21, 1922, was also given thorough consideration.

It was further ascertained that in addition to the work done by the Stoker Department of the Westinghouse Electric & Manufacturing Company, the Sanford Riley Stoker Company had also been giving careful study to this problem, same being largely in the hands of Mr. A. H. Blackburn and Mr. R. L. Beers. Mr. Beers is now chief engineer of the Detroit Stoker Company. Their work has been based upon the formulæ developed by Mr. Menzin in his paper above referred to.

After a careful comparison of the results obtained by Mr. Foresman, Mr. Blackburn and Mr. Beers, by plotting the two sets of results obtained side by side, a very slight variation in results was noted. The slight variations were easily accounted for by comparing the different assumptions used. It was, therefore, decided to adopt Mr. Foresman's curves for further work.

It is, of course, fully understood that there are many variables entering this problem, prominent among which are draft loss through the boiler, draft required to produce the required velocity up to the boiler damper, draft loss in the chimney itself; draft loss in the breeching, and effect of altitude. The weight of gases delivered to boiler and percentage of heat rejected to the chimney varies with varying percentages of CO2 and different chimney temperatures. This variation may be one of very high degree.

It is apparent from the above that many assumptions must be made in the preparation of charts such as are to follow, and Mr. Foresman has, the committee feels, tried to keep on the safe side in making his assumptions. The method employed by Mr. Foresman for determining the data and plotting his curves is as follows:

### Assumptions for Stack Calculations

It will be recognized that before the dimensions of a stack can be determined, it is necessary to make a number of assumptions on which to base the calculations. These assumptions are such that they vary quite widely and so rapidly that they do not remain constant on one piece of apparatus or with one fuel for any appreciable length of time. It is, therefore, necessary that the values of these quantities must be determined from actual experience on stoking apparatus, boilers and necessary auxiliary ducts, etc.

The assumptions made are relatively safe and are as follows:

 Efficiency—68 percent at 100 percent and 200 percent rating of the boilers.

- Efficiency-63 percent at 300 percent rating of the boilers. (2)
- (3) CO₂-9 percent in the stack at 100 percent rating.
- CO_10 percent in the stack at 200 percent rating. (4)
- (5) CO_11 percent in the stack at 300 percent rating.
- (6) (7)
- Stack temperature—450 degrees at 100 percent rating. Stack temperature—525 degrees F. at 200 percent rating. Stack temperature—600 degrees F. at 300 percent rating.
- (8)
- (9) Initial air temperature—60 degrees F.
   (10) Barometric pressure—14.7 pounds per square inch.

### CURVES A AND F

The calculation of the required data for these curves is quite simple and can be found in "Steam" page 156. The abscissæ are boiler heating surfaces and the ordinates are cubic feet of flue gas. This latter is not shown on the curve. The ratings were calculated from the assumptions shown above and are plotted as "rating curves."

Weight of coal for a given rating=

(1) 
$$W_1 = \frac{PR \ 970.4 \ (34.5)}{CE} = 33,478.8 \times \frac{PR}{CE}$$

where  $W_1 =$  weight of fuel, pounds. P = horsepower rating of the boiler.

- R = percent rated capacity. C = B.T.U. of fuel as fired.

E = efficiency of boiler and stoker.

An average figure was determined for the combustible value of the fuel. This permits of employing the curves with any coal as no reference is made to its calorific value. The actual data are in the form of "pounds of flue gas per horsepower hour developed" due consideration being given to the varying weight of gas per pound of fuel burned, due to the varying CO2.

The limits of error of such a procedure are within the limits of error of the assumptions made.

The weight of gas per minute to burn the above coal was determined by:

$$W_{z} = \frac{3.036}{60} \frac{(N)}{(CO_{z} + CO)} C W_{1} + W_{2}$$

$$W_{z} = .506 C W_{1} \frac{(N)}{(CO_{z} + CO)} - W_{2}$$

 $W_2 =$  weight of gas per minute to burn the required coal. W₃ = weight of combustibles burned.

(

^{*}Report of sub-committee of the joint American Boiler Manufacturers' Association and Stoker Manufacturers' Association committee read at the thirty-fifth annual convention of the American Boiler Manufacturers' Asso-ciation at The Homestead, Hot Springs, Va., June 5.

[†]The Wickes Boiler Company, Saginaw, Mich.

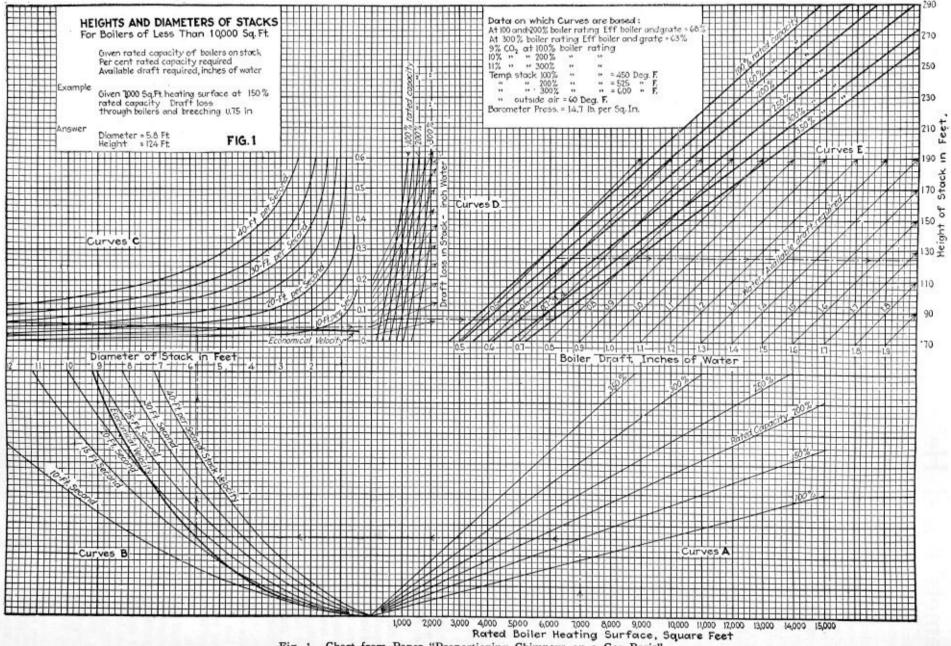

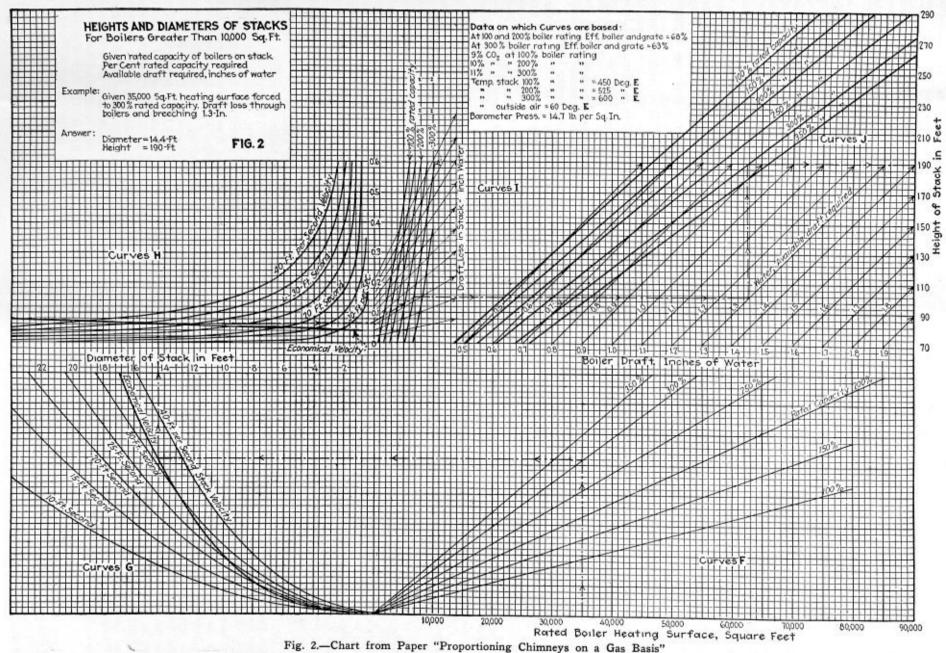

Fig. 1.-Chart from Paper "Proportioning Chimneys on a Gas Basis"

202

CO₂ = percent CO₂ CO = percent CO.

C = percent carbon burned.

To convert the weight of gas into cubic feet at the stack temperatures.

(3) 
$$V_1 \equiv W_2 (V_2)$$

CURVES B AND E

In these curves the same ordinates are used, namely: "cubic feet of flue gas," the temperatures of the gas being as shown above. The abscissæ are "diameters of stacks." It is assumed that all stacks are cylindrical.

With the volume  $(V_1)$  and the velocity given it is very easy to calculate the area or diameter required.

(4) 
$$A = \frac{\pi D^2}{4}$$

A = cross sectional area of the stack at the top.

D = Diameter of the stack at the top.

(5)  $S = \frac{V_1}{60_A}$ 

S = velocity of the gas up the stack.

The above calculation is made for a great number of cases and the velocity curves are plotted.

The economical velocity curve has been determined from constructional consideration. It is so proportioned that the stack may be quite easily built. The authority for these proportions can not be located but it is believed that it was taken from some article in *Mechanical Engineering*.

### CURVES C AND H

These are velocity curves plotted with stack diameters as abscissæ and draft loss per 100 feet of height as ordinates. The authority for this is given in A.S.M.E. bulletin No. 1518, from which this curve was copied with the necessary modifications.

### Curves D and I

The plotting of the remaining curves is quite complicated as there is no direct connection between the computation of stack diameters and stack heights. In order to accomplish this it was necessary to devise a transition curve as shown in curves D and I. The ordinates of these curves are "Total Internal Draft Losses in the Stacks," but for curves C and H these same ordinates are "Internal Draft Losses per 100 Foot Height."

The rating curves (D and I) are drawn to any given slope. This is immaterial as it is the intersection of these curves and the diagonal "Draft Loss in Stack" curves that is of value, and this intersection would fall at the required ordinate irrespective of the slope of the "rating curves."

The diagonal "Draft Loss in Stack" curves (D and I) have been determined by calculating an average height of stack for the various ratings and velocities; then determining therefrom the internal draft losses, and then plotting these points on the "rating curves" against the "Total Internal Stack Loss" as ordinates. These points then determine the slope of the "Draft Loss in Stack" curves and they can then be plotted. It will be noted that although the left hand ends of these diagonal lines represent the "Internal Loss per 100 Foot of Height," their intersection with the "rating curves," when referred to the ordinate gives the average "Total Internal Stack Loss" for the various ratings.

### CURVES E AND J

Curves D and I ordinates are "Total Internal Draft Loss," and this quantity plus the "Available Draft Required" equals the "Total Draft."

It will be noted that this is taken care of by the direction

of the "Available Draft Required" curves. It is available draft that is necessary to remove the gases, but stacks must be designed on the basis of total draft.

These "Rated Capacity Curves" (E and J) are determined as follows: Assume a given problem and follow the curves through as though the curves were complete except that the height must be calculated. Assume any "Available Draft." Follow a line through until the given "Available Draft" is reached then draw a vertical line from that intersection. By calculation the height is known and from that height draw a horizontal line and its intersection with the above vertical line gives a point on the "Rated Capacity Curves." This must be done for a great many ratings, and with varying conditions of draft. The points thus obtained determine the "Rated Capacity Curves" (E and J). The "rating curves" E and J could also be plotted as

The "rating curves" E and J could also be plotted as temperature curves showing the total draft produced by a given height of stack at varying temperatures as it is assumed that definite temperatures are obtained at these ratings. Inasmuch as lower temperatures are obtained at the lower ratings, it is evident that for a given draft loss a higher stack will be necessary for the lower rating.

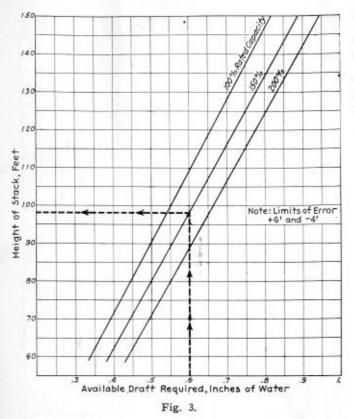

It will be noted that apparently a higher stack is required for low ratings than for high ratings. This is not true, of course, as the draft loss through boilers and breeching is so much less for low ratings than for high ratings. The low rating curves should be above the high rating curves as the internal temperature will be less in the former, and the amount of excess air will be somewhat greater. Both conditions being conducive to less draft and greater height.

At first glance the charts may seem to be rather complex, but by following a few cases through it will quickly be seen that the charts are very simple to use. They have been used by the Westinghouse Company for six months, have been checked against actual stack performance repeatedly, and in every case have worked out well. Mr. Foresman described the use of the curves as follows:

Chart No. 1 (Fig. 1) is for boilers of less than 10,000 square feet heating surface, while No. 2 (Fig. 2) is for the boilers of 10,000 and upward. Both charts contain notations of certain air and gas conditions that are assumed for basing these curves. It is necessary to know the amount of connected heating surface in square feet as well as the draft pressure required to carry the gases through the boilers and breechings. Any desired velocity of gases in the stacks may be used; the curves at B and C, Fig. 1, contain lines that represent the *economical stack velocity* as the average of commercial conditions indicates. The stack diameter, draft loss in stack and height of stack may be determined from curves C, D and E.

*Example No. 1*, as noted on Chart No. 1, assumes that the evaporating surface of the boilers on the stack is 7,000 square feet, the draft loss being 0.75 inch of water for boilers and breechings, working at 150 percent rated capacity. Find diameter and height at the economical velocity.

The chart indicates the line from curves A, starting at 7,000 square feet heating surface and rising vertically to the 150 percent rating line, moving horizontally from there to the curves at B, where the *economical velocity* is encountered. The stack diameter of 5.8 feet is here indicated. Moving vertically we come to the *same velocity* in curves C, which is the line of *economical velocity*, and then move horizontally to curves D. After touching curves D at the vertical starting line, then move parallel to the inclined direction lines shown with arrowheads until the 150 percent rating is encountered. From this point move horizontally to the curves E, where a draft loss of 0.75 inch is obtained, which comes midway between inclined lines 0.7 and 0.8 noted by arrowheads. From this point rise vertically to the 150 percent rating and read the stack height at the scale to the right, which in this case is 124 feet.

JULY, 1923

The draft caused by stack loss is shown at curves D. This is 0.045 inch of water. The total draft pressure required is the sum of this stack loss and 0.75 inch required for boiler breechings, which totals 0.795 inch.

for boiler breechings, which totals 0.795 inch. Example No. 2. Suppose it is required to carry 175 percent rating on the same stack, how much would the stack height require to be increased, assuming that the draft pressure required for 175 percent rating is 1.05 inches of water? Rising vertically from 7,000 square feet to a point midway between the 150 percent and 200 percent rating lines, we then move horizontally to the stack diameter as in Example 1, which gives a velocity of 20 feet per second. We then rise vertically to the 20 feet per second line, curves C, and move horizontally to the curves D of stack loss, which amounts to 0.06 inch. Moving obliquely with the direction lines to 175 percent rating, and then horizontally to a draft-pressure requirement of 1.05 inches (1.05 - 0.06 = 0.99) on the diagonal lines) which is obtained from the oblique line in curves E, we then rise vertically to the line of 175 percent rating and obtain a stack height of 166 feet, read at the right. This would mean an increase in height of 166 minus 124, or 42 feet.

Example No. 3. Assume the same boilers and losses, at 150 percent rating, what stack height and diameter would be required for a velocity of 25 feet per second? The diameter taken from curve B is 4.8 feet. The stack loss in this case is 0.115 inch from curves D. The boiler draft requirement is 0.75 inch as outlined as a condition in Example No. 1. Using 150 percent rating, we find that a stack height of 146 feet is necessary.

*Example No. 4.* Suppose the same boilers were to be placed on a stack  $6\frac{1}{2}$  feet in diameter and 230 feet high and assuming that the loss of the boilers and breechings at various ratings varied as the square of the ratings, find the ratings to which the boiler may be forced. Taking a reading with 150 percent rating and 0.75 inch draft pressure required for boilers and breechings, we find that a  $6\frac{1}{2}$  foot stack gives 13.75 feet per second velocity, curves B, with a stack loss of 0.03 inch. The stack height is 116 feet. Now assuming a 200 percent rating and a loss of boiler and breechings of

1.4 inches, we obtain the *economical velocity*, which is 18 feet per second; the loss in the stack is 0.045 inch and the stack height is 228 feet. The stack would, therefore, be satisfactory for 200 percent rating.

In order, however, to make the matter even more simple the following tables have been prepared from the curves, so that anyone preferring to use tables in place of curves may do so, and, of course, obtain the same results.

The committee recommends that for horizontal breechings the sectional area should be 20 percent larger than that of the stack—this to allow for increased friction in a horizontal over a vertical column, as well as reduction of area by accumulation of dust on the bottom of the breeching.

The committee believes it has been the practice of the majority of return tubular boiler manufacturers to proportion stack areas to the aggregate area of tubes. It is quite general practice in determining the area of the stack to provide approximately 20 percent increase of area over the aggregate area of the tubes. From the curves (Figs. 3 to 6) it is apparent that the diameter of stacks determined in this way is sufficient for operating the boilers at 150 percent of their rated capacity. The height of stacks for return tubular boilers has ranged from 25 feet on smaller boilers, say 30 inches in diameter by 8 feet long, to 60 feet on boilers 72 inches in diameter by 18 feet long. These heights provide

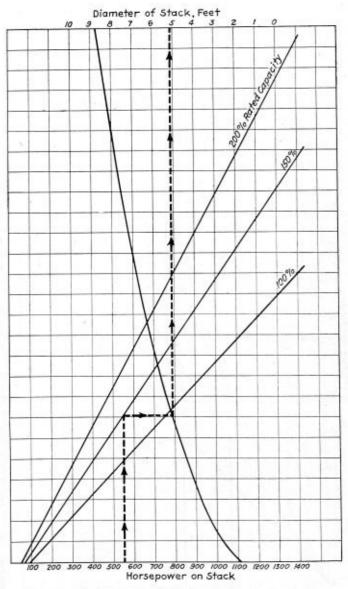

Fig. 4.

draft sufficient for operating boilers at about rating when burning coarse bituminous coal, but are inadequate for high ratings and for burning the finer grades of bituminous coal, and, of course, the fine grades of anthracite coal. This is quite clearly displayed in the charts.

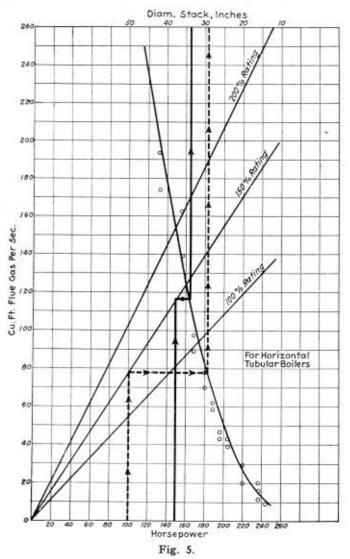

It must be borne in mind that present practice is to place these stacks on top of boilers so that 8 feet to 12 feet should be added when height from the grate is considered.

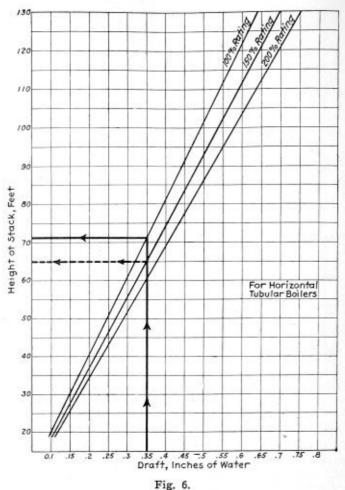

Because of the tube area and the resulting high frictional loss through the tubes, extreme ratings of horizontal return tubular boilers are not possible, and commercially are seldom sought. There are times, however, when 200 percent of rating is sought and there are times when frictional resistance through the fuel bed is such that higher chimneys than standard are sought. The curves have been prepared using Mr. Menzin's formulae and gas velocities for use with horizontal return tubular boilers.

Assumed diameter	curves		
Rating	100	150	200
Efficiency, percent	65	65	63
CO ₂	8	9	10
Stack temperature	450	500	550
Pounds of gas	85	77	73

The small circles upon the velocity curve represent present day practice of the horizontal return tubular boiler builders, and it is noted are in pretty close accord with Mr. Menzin's velocity curve.

This curve is represented in simplified form and its use is readily understandable. Taking an example: a 72-inch by 18-foot return tubular boiler (or 150 horsepower) is indicated with a dotted line and arrowheads, as follows:

Rising vertically from 150 horsepower to the 150 percent rating line, thence horizontally to the high velocity line, thence vertically, we have the diameter of stack required, 34 inches. Then knowing the draft required in the furnace and the draft drop through boiler to stack, the height of stack required is very easily obtainable. Under ordinary conditions of 100 percent rating, with coarse bituminous coals from 0.3 inch to 0.35 inch will satisfy; but high drafts are necessary at higher ratings, or with small coals, or any other condition which increases resistance.

In conclusion I wish to make full acknowledgment of the assistance, in the preparation of this report, of Mr. A. G. Pratt, Mr. Starr H. Barnum, Mr. A. H. Blackburn, Mr. R. L. Beers, Mr. R. A. Foresman, Mr. Harry H. Bates and Mr. G. L. Bouton.

Inasinuch as the Stoker Manufacturers' Association has considered this report at its annual meeting and adopted as its standard the recommendations of the committee, it is hoped this association will do likewise. If the members of both associations adopt the method of proportioning chimneys set forth in the report, and put it into general practice, it is felt that it will soon become common practice among architects and consulting engineers, and undoubtedly afford relief to us all from troubles caused by lack of proper chimney proportioning.

## Stack Tables for Reference (From Westinghouse Chart)

HEIGHT OF STACK FOR AVERAGE INSTALLATIONS (SEA LEVEL) Forced Draft Stokers

Per Cent Rating		150	200	250	300

At a recent joint conference between the officers of the International Railway Fuel Association and those of the Master Boiler Makers' Association it was decided that future conflicts between the conventions of these associations would be avoided. As a result of this agreement, the 1924 convention of the Master Boiler Makers will be held at the Hotel Sherman, Chicago, May 20 to 23, 1924, the week before that of the Fuel Association.

With the two associations co-operating in this manner, it will be possible for the manufacturers of railroad and boiler supplies and equipment to arrange a single complete exhibit which can be transferred from one convention to the other, thus eliminating the necessity of providing and conducting two complete exhibits at the same time. It will also be possible for members who are required to attend both conventions to do justice to each of them.

From time to time attention is called through news items and editorials in trade journals devoted to the steel industry to the ever increasing extent of tank fabrication in boiler manufacturing plants. It is quite logical that the industry equipped as it is for heavy plate work should turn its production facilities to this lucrative allied field especially where it is possible to utilize available plant capacity for this purpose without expansion.

At present the greatest tank demand seems to be for oil storage, undoubtedly due to the recent tremendous expansion of certain of the country's oil fields.

During the first week of July a boiler and tank manufacturing concern located in the Middle West received a single order for 20 tanks of 55,000 barrels' capacity, another company this same week received orders for 30 tanks, while 5 tanks of 80,000 barrels' capacity were contracted for by a third company. In all, about 80 large sized tanks in capacities up to 80,000 barrels were ordered in this period. The steel plate orders for work of this character were correspondingly large. In this connection the quarterly plate requirements of one company for tank work alone was 5,400 tons.

A great deal of this business that did not go to the boiler works could no doubt be profitably contracted for by them especially during the summer months when boiler production usually falls off. In fact, heavy plate or tank work is a real asset to the business of any shop throughout the year.

The National Board of Boiler and Pressure Vessel Inspectors is to be congratulated upon the excellent progress which it has made in the past year. A year ago 503 boilers were registered with the Board by 18 concerns; today 6,387 boilers are registered by 35 firms making an increase for the year of approximately 1200 percent. No less than 14 states and half a dozen cities will accept without question boilers stamped with the National Board stamp and no instance has been recorded where a boiler stamped "National Board" was not a Code boiler.

Following its rapid growth during the past year, the National Board is now about to investigate the activities of dealers in second-hand boilers with the object of putting a stop to dangerous practices in this line of business. It is believed that rules and regulations governing the use of second-hand boilers can easily be established which will be as effective and as uniform as those for the manufacture and inspection of new boilers. In addition to this, the National Board will take into consideration the adoption of rules covering air and other pressure vessels, as it is found that explosions from such vessels are even more widespread and destructive than in the case of boilers.

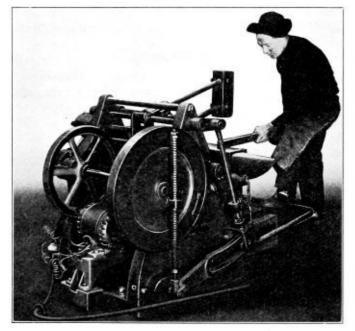

It is gratifying that this branch of the boiler making industry is making such rapid progress and it is hoped that its future efforts will receive even more substantial support from manufacturers and dealers alike in future.

# Engineering Specialties for Boiler Making

New Tools, Machinery, Appliances and Supplies for the Boiler Shop and Improved Fittings for Boilers

## General Utility Power Smithing Hammer

A POWER-DRIVEN hammer intended particularly for use on forging work ordinarily performed under handswung sledges and too small to be done under steam hammers, is shown in the accompanying illustration. The hammer is termed a "mechanical helper," since it replaces the one or two man employed as strikers at each anvil. The same

Power Hammer for Forging Work

hand tools that the smith ordinarily employs are used with the hammer, without the need of special tools and dies. The hammer, which is stated to greatly increase the capacity and the output per anvil, has recently been placed on the American market by the Blacker Engineering Co., Inc., Grand Central Terminal, New York, N. Y.

The machine is rated to handle material up to  $2\frac{1}{2}$  inches thick, although even larger sizes can be cared for. The hammer itself is under the control of the smith, so that either a light or heavy blow can be struck. The force of the blow varies directly with the depression of the treadle extending around the anvil. It is stated that the maximum blow is about four times as heavy as that delivered by a human striker, and that the machine attains a rate of 140 blows per minute.

An important feature of the hammer is the lateral traverse motion that can be given to the hammer itself. This motion is controlled by a winged foot lever located at the right of the anvil and enabling the head to be traveled along the face of the anvil to the desired point.

An anvil and a block of special design to suit the hammer are furnished. The base of the anvil is planed and adjusting screws are provided on the stand, to enable the anvil to be moved forward or backward to get the proper position under the hammer.

The hammer requires only 1 horsepower to drive it. It can be run by means of a belt from a lineshaft, being furnished with tight and loose pulleys 15 inches in diameter for this work. A more compact unit is the one driven by an individual motor, as illustrated. The motor is mounted on a small stand on the base and geared to a large driving gear placed on the main shaft. The hammer alone weighs 1,300 pounds, the anvil 560 pounds, and the stand 336 pounds.

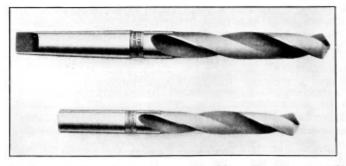

## A New Development in Drill Making

FOR the past few years high speed drills have been made by two methods, first, by twisting a flat bar, or second, by milling from a round bar. The first involves a hot working process to form the flutes, followed in turn by a machining and a twisting process, or by a simple twisting process without the machining. In both cases the web is usually not central and efforts are made to return it to the correct position by a straightening process, a flute grinding process, or by both.

In spite of the additional toughness imparted to the drill by these methods, the second type of drill made from the full round bar by the milling process, has continued to be the one made and sold in largest quantities, and therefore the one most suitable to the general requirements of the metalworking industry.

The continued preponderance of the milled type of drill may therefore be attributed to the fact that the webs of such drills are centrally located by the milling machine. The drills are uniform and will therefore drill more uniform holes.

The drill point grinding machine insures that points of drills are ground correctly, and such machines should be in

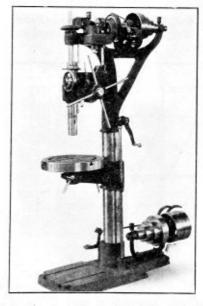

Cle-forge Drills Designed to Combine Toughness and Accuracy

more general use than they are. This machine is, however, only a machine and can grind correctly only such drills as are made accurately and uniformly. If the web of a drill is not central, the point of the drill cannot be accurately ground in a point grinding machine. Drills with the web off center can be ground out at the point so as to bring the web central at that place, but this is a more skilled operation than point grinding by hand and it is one which is seldom, if ever, well, done in the average machine shop. It therefore follows that the ideal twist drill is one having the toughness of the hot-worked drill and the accuracy of the milled drill. It enables drills to be properly ground by machine and assists in removing the prejudice which apparently exists among mechanics against using these machines.

As a large manufacturer of both milled and forged drills the Cleveland Twist Drill Company, Cleveland, Ohio, has been experimenting with a view to placing on the market a single drill which would embody the advantages known to be possessed in part by the forged drill and in part by the milled drill. A process, said to accomplish this result, has been perfected and given the trade name Cle-forge. Cle-forge drills are hot worked where necessary to impart toughness and are afterward machined in the same manner as a milled drill. In fact they cannot be distinguished from the former milled product by mechanical inspection. Briefly Cle-forge drills are intended to unite in one tool all the advantages of both forged and milled drills so that their cutting quality and strength will surpass that of any former type of forged drill and their accuracy be equal to that of the milled drill.

## Redesigned Vertical Drilling Machine

THE 20-in. vertical drilling machine illustrated has been recently redesigned by the Superior Machine Tool Company, Kokomo, Ind., to include bronze bushings, back gears, geared feed and wheel and pilot feeds. Flexibility is secured by the new design and with the unit method of assembly with all parts made on an interchangeable sys-

Superior 20-inch Vertical Drilling Machine

tem, the machine may be converted or reassembled to meet varying requirements.

The feed box is provided with steel gears heat treated, reduction being obtained by a bronze worm and gear running in oil. Three feeds are obtainable by shifting a key in the feed box and three additional feeds by a sliding gear on the top shaft.

The column is well proportioned as shown in the illustration, being reinforced at sections subject to heavy strains. The drive provides for a 2-in. belt and pulley and 234-in. belt on the counter pulley, which gives all necessary power for drilling within the capacity of the machine. Ample provision for lubrication is afforded for all working bearings. This machine can be adapted for motor drive with motor speeds varying from 750 to 1,800 r.p.m.

The height of the machine to the top of the pulley is 74 in., the spindle being  $41\frac{1}{2}$  in, above the base. The distance from the table to the spindle is 26 in., the traverse of the spindle sleeve being  $8\frac{1}{2}$  in. and the traverse of the table  $23\frac{1}{4}$  in. This machine drills to the center of a  $20\frac{1}{4}$ -in. circle. Six spindle feeds from .005 to .018 in. per rev. are available. When belt driven, a driving pulley 9 in. by 3 in. running at a speed of 450 r.p.m. is used. This gives four direct spindle speeds from 970 to 875 r.p.m. and, with the back gears in, four additional speeds from 25 to 226 r.p.m. can be obtained. A one horsepower motor is required if the machine is to be motor driven.

## A High Carbon Welding Metal

ELDING has proven its value in railroad applications not only in maintenance, construction and repairs but also as a reclamation medium particularly on low carbon steel parts. The reclaiming and maintenance of high carbon steel parts such as buffer castings, frog points, steel tires, etc., have somewhat suffered due to the fact that a suitable welding metal was not generally available.

The Page Steel & Wire Company, Bridgeport, Conn., has perfected a welding metal, the carbon analysis of which is practically 100 percent for welding high carbon parts by either the oxyacetylene or electric arc welding process.

The principal application of Page high carbon welding rods and electrodes is for the building up of worn surfaces where a high resistance to abrasive wear is desired. In electric arc welding this electrode maintains a stable and uniform arc. In gas welding the metal flows smoothly. With either process the finished weld may be ground but is not readily machinable.

TESTS OF WELD DEPOSITS ON .42 CARB	ON STEEL.
Original metal— Carbon Brinell hardness test. Thickness of welded layer.	
Carbon	Brinell hardness test
Outer surface of deposit. At a depth of 1/16 in. from top At a depth of 3/32 in. from top At a depth of 3/16 in. from top	56 66.2 57 55.6

The table shows a typical result of weld deposits when made on a steel of .42 carbon content indicating wearing qualities that are more than equal to the original material.

### TRADE PUBLICATIONS

TWIST DRILLS AND REAMERS.—The Latrobe Tool Company, Latrobe, Pa., has issued a catalogue of 112 pages listing and illustrating its line of high speed twist drills and reamers.

BOILERS.—The Lebanon Boiler Works, Lebanon, Pa., has issued Bulletin 23-A which is a 23-page booklet containing a complete illustrated description of the Uniflow improved return tubular boiler; also illustrations of typical Uniflow installations and tables showing the absorption efficiency of fire tubes, horsepower ratings, CO₂ losses, etc.

PREVENTION OF FOAMING.—An instruction booklet entitled "Foaming, Its Cause and Prevention," written particularly for the benefit of enginemen and firemen, has been issued by the Bird-Archer Company, New York. The text sets forth the principle on which anti-foaming compound operates to prevent foaming and explains clearly the reasons for the simple instructions given for its successful use.

## Questions and Answers for Boiler Makers

Information for Those Who Design, Construct, Erect, Inspect and Repair Boilers—Practical Boiler Shop Problems

Conducted by C. B. Lindstrom

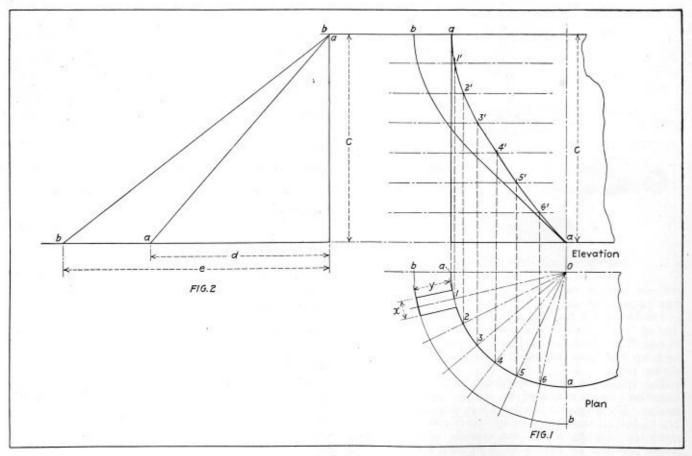

This department is open to subscribers of THE BOILER MAKER for the purpose of helping those who desire assistance on practical boiler shop problems. All questions should be definitely stated and clearly written in ink, or typewritten, on one side of the paper, and sketches furnished if necessary. Inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

## Helical Stairs and Hemispherical Head Developments

Q.--Would you kindly tell me how to lay out a pair of winding stairs. Radius to inside of stairs, 49 feet 8 inches; arc length that stairs are to go around tank, 58 feet 10 inches. There are 55 steps or 56 treads. Height of tank, 48 feet 10 inches. This makes about one-quarter turn around tank. Please tell me how to find the length of the two channels that form the stairs and how to lay out the channels. Also will you give the layout and development of a hemispherical tank bottom in the next issue of THE BOILER MAKER having a radius of 7 feet inside and made of 8 plates 5/16 inch. thick.-A. P.

A.—The development of the helix for the inside and outside frames as required for a helical stair making a quarter turn around the tank, involves the drawing of a partial plan and elevation as shown in Fig. 1. With o as a center and o-a and o-b as radii (taken from point o to the inside surface of the frames) draw the arcs a-a and b-b in the plan. These arcs represent the path of the helical curves of the frames as they would appear in looking directly down on the tank. Divide one of the arcs into the required number of step divisions, but in this case to simplify the solution seven divisions are used. Divide the height C of the tank into the same number of parts, and through the points so located draw the horizontal projectors. From 1, 2, 3, 4, etc., draw vertical projectors to intersect the horizontal ones of the elevation, thus locating points 1', 2', 3', 4', etc., which are the required points for drawing in the helix for the frame. The outside helix for the outer frame is developed in the same way.

The lengths of the helices are determined in Fig. 2. The height c and the base dimensions d and e form two right angle triangles of which d equals the arc length a-a of the plan and e equals the arc length b-b. The hypotenuse a-a of Fig. 2 is the required length of the channel near the tank and b-b the length of the outside channel support. A small

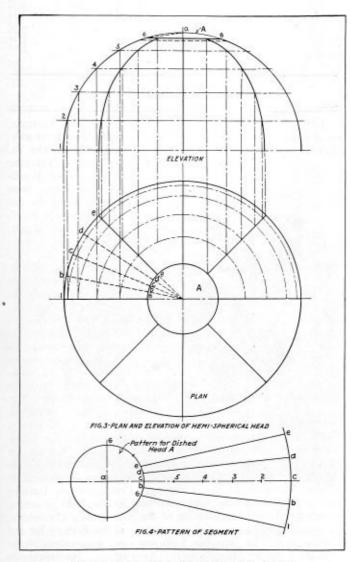

Partial Plan, Elevation and True Lengths of Lines in Spiral Stair Development

allowance should be made in these lengths for working up the channels to the required shape.

The step layout consists of transferring the respective dimensions x and y of Fig. 1 to form a template, from which the remaining steps can be marked off.

#### DEVELOPMENT OF HEMISPHERICAL HEAD

A simple solution for developing a hemispherical head is given in Figs. 3 and 4. The plan is divided into the required number of segments and the bottom is finished with

Simple Layout for Hemispherical Head

a bumped head, A. The outer curve  $I-\delta$  of the segment is is divided into a number of equal divisions as required for developing the pattern or a better way is to run off the length with a traveling wheel. The respective dimensions for the head and segments should be laid off to the center of the plate, for in working the plate there are certain changes that occur for which plate allowances would otherwise be essential in the pattern layouts. At the center of the plate no change occurs and a pattern laid off therefrom will give the required size of the pattern.

The arc length *i-e* of the plan is divided into a number of parts for setting off the stretchout at the bottom of the segment pattern.

It will be noted that the inner arcs of the segment as taken on the edge lines are shown developed in the elevation. This part of the work is not essential. In Fig. 4, the pattern for the bumped head is drawn with a radius equal to a-6 of the elevation of Fig. 3. Divide  $\frac{1}{8}$ of the circle into 4 equal parts, as shown from 6 to e and on the line c-c set off the arc length I-6 of the elevation, Fig. 3. From point c, Fig. 4, set off the arc length I-6of the plan view and from points b and d of the circle, Fig. 4, set off the length c-c. From points 6 and e set off the same length to intersect the arcs drawn from b and d at the bottom of the pattern, thus locating the points I and e. Draw in the curve through I-b, c-d and e and allow for the side lap.

### A Peculiar Boiler Accident

Q.-We have a floating hoister, as it is called at our yard, which was sent out to float a sunken vessel in the Delaware River. The hoister finally sank during the operation. When it was recovered and brought back to the yard, the engineer related his experience to me. He said that when the hoister sank he was positive that he had nearly 100 pounds of steam up and of course she would blow at 100, which he claimed would help some. He also said that all the tubes were shot and that a new set of 206 two-inch tubes would be required to put the boiler in condition again after the sudden contact with cold water. I, having my doubts, but not being sure, had two men fill the boiler with water (barreled up) and no signs of any lesks were visible. I had the water dropped down the gauge glass and a fire started. According to the amount of fuel at hand, I was only able to get up 60 pounds steam pressure and, at this pressure, there were no signs of any tube blow outs or otherwise. In fact, one tube had been plugged for over a year and that tube in particular was as good as when first put in. In not being able to find any defects I am writing you for your opinicn. Where would the steam under 130 pounds pressure go in coming into sudden contact with cold river water? This boiler had two safety valves but boiler sank pretty fast with hoister. Why did not the boiler explode? There have been many differences of opinion of this accident, so I thought that perhaps you could tell me.—F. C. C.

A.—The fact that the boiler did not explode under the conditions mentioned shows that it was strong enough to withstand the additional stresses arising from the rapid cooling of the boiler materials.

As the hoister sank the water extinguished the fire in the firebox before the boiler was entirely enveloped, therefore, the only possibility of a greater evaporation of water into steam was from a sudden release of the pressure due to a rupture of the boiler shell, heads or tubes, which did not occur.

The violence of a boiler explosion arises from the stored energy in the heated water, which, upon being released, expands into a much larger volume.

The steam in the boiler in this instance condensed as the plate and heated water cooled off.

## Question on Tank Supports

Q.--Will you please give some more light on the formula  $\frac{\sigma^*}{8^4 + 10^4}$  for finding the load on the beam has been derived. This formula will be found in the March, 1923, issue of THE BOILER MAKER, Questions and Answers column, "Tank Support Calculations."-T. L.

A.—The formula for computing the proportion of the load on each span is based on the deflection of the structural member of each span. The derivation of the formula is based on higher mathematics. The formula is used in practice, and its application is the important consideration.

## Number of Courses in Standard Horizontal Return Tubular Boilers

Q.—As I am a practical boiler maker and a subscriber of THE BOILER MAKER I want you to answer this question for me by return mail, if you please. What is the best type of boiler for stationary work, at two course boiler with return flues and a quadruple riveted butt seam, or a three-course boiler with return flues and a quadruple riveted butt seam? These boilers are 200 horsepower and 20 feet long.—R. S.

A —Horizontal return tubular boilers of this size are ordinarily built of three courses. The three-course boiler for such a length is the best for the reason that the narrower sheets are more easily fabricated and that the circumferential seams give the necessary rigidity in the support of the shell. The standard boiler sizes of this type 60 inches and over in diameter are made in three courses.

## PERSONALS

Edwards R. Fish was born at Stone Mountain, Georgia, on August 4, 1870. He attended public schools in Kentucky, Texas and St. Louis. After his graduation from the St.

Louis Manual Training School he entered Washington University from which he received the degree of Mechanical Engineer in 1892. In March, 1893, he became associated with the Heine Boiler Company in St. Louis and has served that company continuously in various engineering capacities. His activities included testing, design, installation and manufacturing. He is at present a vice-president of this company and a member of the board of directors. Mr. Fish has been an active

E. R. Fish

member of the American Society of Mechanical Engineers since 1914. He has been a member of the Boiler Code Committee since 1918 and chairman of the Sub-Committee on Air Tanks and Pressure Vessels since its formation in 1919. He is also a member of the Main Committee on Power Test Codes, chairman of the Individual Committee on Boilers, and a delegate of the Society to the American Engineering Council. At a recent meeting of the Nominating Committee, he was named as one of the managers of the Society for the coming year. In June Mr. Fish was elected president of the American Boiler Manufacturers' Association. He represents the Association in the American Uniform Boiler-Law Society. He is past-president of the Engineers Club of St. Louis and for many years has been active in its work.

C. C. Rosser, who for many years has been connected with the Detroit Seamless Steel Tube Company, has been appointed district sales manager, with offices at 1206 Guardian Building, Cleveland, Ohio.

### OBITUARY

John B. Wolters, for the last few years United States inspector of boilers and machinery for the Bureau of Navigation, Department of Commerce, died in San Francisco recently, after a long illness. He was well known along the water front. He is survived by a widow, Mrs. May Wolters. and a son, John B. Wolters, Jr., boiler inspector for the New York Underwriters.

## Explosion of Vertical Tubular Boiler

T HE recent explosion of the vertical tubular boiler, shown by Fig. 1, at Algoma, Wisconsin, emphasized the reasonableness of modern requirements dealing with boilers of that kind, and that the pressure carried in the older boilers should be reduced as their age and changed conditions may necessitate.

The boiler which exploded was operated, and presumably owned by a contractor constructing a new bridge at Fourth street, in that city, and not only were the employes exposed to the danger of injury, but the public, whose safety must be protected by the use of the greatest precautions, had clearly recognized rights in the vicinity. The papers report the presence of numerous persons within two hundred yards of the place at the time of the accident, and three people

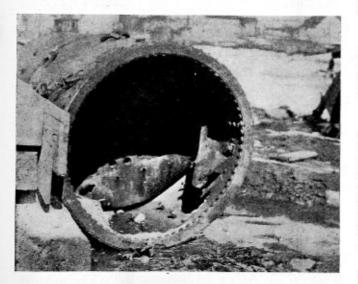

Fig. 1.-Shell of Boiler After the Explosion

are said to have been within six feet of the boiler not more than five minutes preceding the explosion.

#### CAUSE OF FAILURE

The explosion was the direct result of the failure of the firebox sheet, which pulled free from the staybolts, and split vertically. A part of the sheet curled up against the firebox tube sheet, while another part was projected downward around the mudring. This left an opening about one-fourth the circumference of the boiler, through which the water and steam were projected, causing the boiler to sky-rocket.

The boiler was projected over 125 feet into the air, and in descending cut the wires carrying high voltage electric current from the High Falls plant to the cities on the north, so that added source of danger required the efforts of the police department to prevent injury to the crowd which quickly gathered.

The loss sustained by those dependent upon the electric current for power and light was considerably greater than the damage which resulted directly from the explosion, as a number of industries in Sturgeon Bay and vicinity were forced to shut down until the wires could be repaired and transmission of current re-established.

The pressure carried at the time of the accident was 125 pounds, and the pressure gage was observed some fifteen

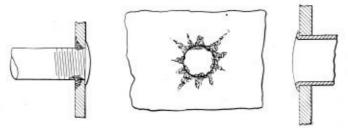

Fig. 2.—One Method of Repairing a Boiler Where Staybolts Have Deteriorated

or twenty minutes before the explosion occurred. So far as could be learned, the boiler had been operated at that pressure for an indefinite time, and is said to have been represented as safe by the party from whom it was purchased.

#### DETAILS OF BOILER

The boiler was 44 inches in diameter by 90 inches in length. The shell plate was constructed of a single sheet  $\frac{1}{4}$  inch in thickness, and the firebox side sheet was made from material of the same gage. The staybolts were  $\frac{3}{4}$  inch in diameter at top of thread, and the pitch at the centers was 8 inches by 8 inches. The safe working pressure, based upon the load permitted on the staybolts by modern rules of boiler construction, was about 34 pounds, if we do not take into consideration the fact that  $\frac{1}{4}$ -inch firebox sheets are not permitted, the minimum being  $\frac{5}{16}$ -inch.

The staybolt heads may have been of sufficient size and properly formed, when the boiler was new, but use and abuse had reduced the size of the heads at the firebox end of the bolts, and many of the heads were badly split, probably the result of redriving. The staybolt holes in the fire-

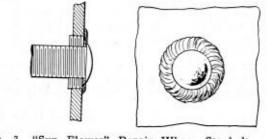

Fig. 3.—"Sun Flower" Repair Where Staybolt and Sheet Have Corroded

box sheet had no doubt been of proper size and threading, but the feed water used at some operation had affected the joint of sheet and staybolt to such an extint that little, if any, holding power remained, as illustrated by Fig. 2. This form of deterioration is not unusual, and may jccpardize the safety. of a well constructed boiler if used with feed water containing certain acids. If but one bolt and the surrounding sheet are affected, temporary repairs may be made by cutting the hole in both inside and outside sheets, after the bolt has been removed, to fit a tube 1 inch or  $1\frac{1}{4}$  inches in diameter. The size of tube necessary will, of course, depend upon the extent to which the sheet has corroded. A repair of this kind is shown by Fig. 2. However, if proper tools are at hand, or if several of the staybolts are to be removed, on account of corrosion of the sheet, it is better to use a sunflower, illustrated by Fig. 3, rather than to use the tube in making repairs. The sunflower is more dependable, and its use avoids the necessity of enlarging the hole in the shell plate.

When a boiler of this type, or, in fact, any waterleg boiler is being retubed, or given other repairs in the shop, the boiler maker on the job may be of real benefit to an indefinite number of people, by examining the sheets and staybolts carefully for corrosion, and by making necessary repairs.

Chicago, Ill.

J. P. MORRISON.

## **Gusset Sheet Layout**

IN my opinion the method of laying out a gusset or slopbarrel sheet, as illustrated on page 182 of the June issue of THE BOILER MAKER, is very good for use on small jobs where the center "X" can be reached with trammel points. It is, however, impractical for the slope course of the average boiler where the taper is comparatively small, since it will be found necessary to make the layout to scale and then transfer it full size to another sheet.

For such a job I much prefer to use simple triangulation as is illustrated on page 236 of the third edition of "Laying Out for Boiler Makers." A little care in working up the triangles will give as accurate a result as could be desired; and when the layout must be made to scale by the former method, the latter will be found much quicker.

Houston, Tex.

R. L. Phelps.

## In the Interest of Better Boiler Inspection

A FEW weeks ago one of the leading railroads of the country has had two disastrous explosions of locomotive boilers, in which the loss of life was great and several persons badly injured. The papers state the cause in both cases as unknown and from this it is plainly seen that someone is withholding the facts.

Why does the public not learn the truth of such a situation. The example of these two explosions would tend to make others more cautious. It is stated that one of the locomotives had just left the shop the day after receiving repairs. Certainly, if this was the case someone was negligent in his work or else the accident was unavoidable. We do know that the locomotives of the country are in a terrible condition, yet they are allowed to operate.

The government not having a force large enough to cope with the situation is at present taking the matter up with Congress to enlarge the staff by 35 more additional inspectors.

There are men holding down the position of boiler inspectors in the shops of the country who are not qualified to hold such responsible positions. There is no rule or regulation whereby the inspector is required to pass an examination as to his ability and fitness to inspect. The laws in many states in regard to inspectors of stationary boilers now require the inspector to pass an examination to show whether he is competent to inspect or not and if not, he is not given authority to inspect. Yet a locomotive boiler carrying from 50 to 100 percent more pressure than a stationary boiler can be inspected by anyone the company puts on the job and the mechanical officer in charge is held responsible.

What authority has a company inspector anyway? He inspects the boiler and notifies the gang foreman or foreman of the defects. The gang foreman or foreman goes over the points mentioned and, if he has time, will do some of the work and, if not he "lets it slide," as the saying goes.

I have seen cases where loose staybolts were allowed to be put in and loose rivets calked up to make them tight. I mean real loose and not merely ones that were sweating. I am at present working in a railroad shop and will say that engines are being operated under conditions that are very unsatisfactory, it being impossible to give them the necessary repairs, owing to the fact that the traffic is exceedingly heavy and must move.

Certainly the traffic should move, but is that any sign that the public and the railroad man should take their lives in their hands in order that traffic be kept on the move? Engines are being operated with many cracked and broken bolts, more than the limit placed in Rule 25 of the Interstate Commerce Commission Rules and Regulations.

Recently we removed 10 cracked staybolts, all located adjacent to each other and old breaks. Electric welds are found that are improperly done, the welder not cleaning the sheets and seams prior to welding in order to obtain clean surfaces but merely sticking the weld on any old way possible.

On boiler test, I have noticed that the crown bolts are not tested at all and only part of the other staybolts. It is time some action was taken to eliminate these dangerous conditions and practices or else we will have more explosions than we have ever had before. The machine work on the engines is no doubt in the same condition.

Olean, N. Y.

### Cost Accounting

C. W. CARTER, JR.

(Continued from page 195)

(2) Administrative and selling overhead is made up of such items as

Donations.

Postage,

Telephone and telegraph. Salaries.

Administrative salaries, etc.

and the rate for this should be determined in the same way as the factory overhead but, instead of charging same on the cost each month it should not be charged on the cost until the order is completed and billed; that is, the administrative and selling overhead is taken care of by the number of hours included in the cost of the contract regardless of the number of productive hours performed during the month that the charge is made.

In conclusion, the writer wishes to say he has endeavored to present a concise article laying down fundamental principles underlying all costs and has purposely not enlarged or gone into the intricacies of cost accounting, the purpose being that no matter how small the plant may be a cost system should be installed.

## Nationwide Investigation Into Apprentice System

Appointment of a committee to make a nation-wide investigation of the apprentice system has been announced by the American Management Association, composed of many of the country's largest industrial enterprises. The committee, headed by L. L. Park, supervisor of welfare, American Locomotive Company, Schenectady, N. Y., was named by the Plant Executives' Division of the Association, of which Sam A. Lewisohn of New York, vice-president of the Miami Copper Company, is chairman.

### ASSOCIATIONS

## SELECTED BOILER PATENTS

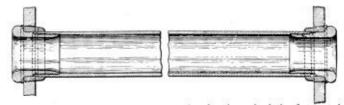

Compiled by

GEORGE A. HUTCHINSON, Patent Attorney, Washington Loan and Trust Building

#### Washington, D. C.

Readers wishing copies of patent papers, or any further information regard-ing any patent described, should correspond with Mr. Hutchinson.

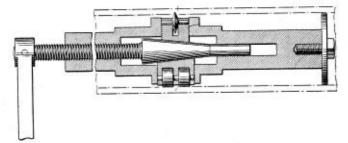

1,457,753. BOILER-FLUE-SETTING DEVICE. FREDERICK SCHMITT, OF OAKLAND, CALIFORNIA. *Claim* 1.—In combination, à flue sheet provided with a flue opening, a flue, a bushing adapted for insertion in said opening from the outer side of said flue sheet and extending slightly beyond the inner side of said flue

sheet so as to form a supporting extension for the end of the flue seated therein, said flue terminating short of said flue sheet, and a clamping and securing member adapted for insertion from the corresponding side into the mouth of the flue. Five claims.

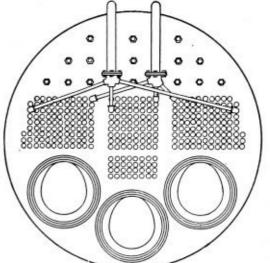

1,457,258. BOILER-TUBE CUTTER. MICHAEL MAHER, OF BAY CITY, MICHIGAN.

Claim.—A tube cutter including a body adapted to be inserted into the tube to be cut, a cylindrical chamber formed in said body, said chamber merging at one end into a blind bore and at the other into a threaded bore, a cone formed at one end with a spindle to fit into said blind bore and at

the other with a threaded shank guided in said threaded bore arranged in said cylindrical chamber, said body adjacent its center between its ends presenting an opening merger into said cylindrical chamber, and a block carrying a circular cutter at one side and formed at the other with a taper-ing face transversely curved and longitudinally arranged in said opening, said tapering face of said block mating with the tapering surface of the cone so as to move laterally when the cone is moved longitudinally.

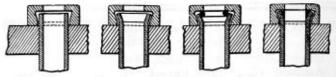

1 453,638. BOILER SUPERHEATER. CYRIL SAMUEL DRAYTON PERRY, OF PORT ARTHUR, ONTARIO, CANADA. Claim.—The combination with a boiler baving a plurality of furnaces of a supported in the upper part and on opposite sides of the furnace fire box, one of said headers constituting the delivery header and being positioned

somewhat higher than the other or receiving header, a plurality of rows of S-shaped superheating coils connecting the headers of each pair, the coils of one row being located between the coils of the adjoining row, a saturated steam supply pipe, a plurality of distributing conduits extending between said supply pipe and the receiving headers of the superheaters.

1,456,145. FERRULE FOR BOILER TUBES. JOSEF PECINKA, OF DEUTSCH-WAGRAM, AUSTRIA.

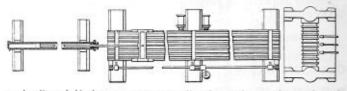

Claim-A boiler tube ferrule comprising a cap of a refractory material provided with an inner circumferential groove having a tapering side wall

provided with an annular recess for the reception of the correspondingly shaped end of the boiler tube protruding from the boiler, and a ring within said annular recess for connecting the end of the tube within and with said ferrule, substantially as described.

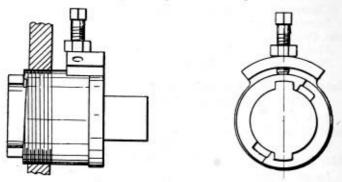

## 1,453,203. TUBE ROLLING MILL. RALPH C. STIEFEL, OF ELL-WOOD CITY, PENNSYLVANIA.

Claim 1.-In a rolling mill, the combination of grooved rolls provided with a large number of working grooves arranged in several series each compris-ing a plurality of grooves, a table in front of said rolls and provided with

a plurality of blank supports corresponding in number to the number of grooves in the rolls which comprise a single series, said table being arranged to be bodily shifted sidewise to bring its blank supports into line with any one of the series of working grooves in the rolls, and means mounted on said table for transferring blanks from one blank support to an adjacent one. 3 Claims.

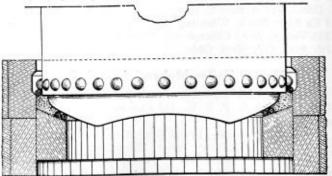

1,457,911. BOILER PLUG. PETER E. McINTOSH AND RUSSELL O'CONNELL, OF KALAMAZOO, MICHIGAN. *Claim* 1.—In a structure of the class described, the combination of a screw bushing with a bearing seat at its outer end and an inner end divided into opposed symmetrical spiral surface with longitudinal slots leading thereto, a plug with a flanged bearing to fit the bearing at the outer end of

the bushing and with longitudinally projecting opposed lugs adapted to pass through the longitudinal slots and engage the said spiral surfaces, a square projection on the plug for turning the same, a transversely projecting plate carrying a curved segment with a series of screw holes, a set screw for insertion through the said segment to lock the plug in closed position, and a lock nut for the set screw, as specified. Six claims.

1.457.281. BOILER CONSTRUCTION. EDGAR KIDWELL, OF MILWAUKEE, WISCONSIN, ASSIGNED TO KIDWELL BOILER COMPANY, OF MILWAUKEE, WISCONSIN, A CORPORATION OF WISCONSIN.

Claim 1.—A boiler having a setting with an opening in the wall thereof, and a drum having its head and a portion of its cylindrical shell loosely entered in the opening, said opening being formed by a ring structure built into the setting and presenting two internal face portions whereof one en-

circles the shell and is in spaced relation thereto and has an annular groove in proximity to the drum head rivets, and whereof the other face portion is inclined and in spaced relation to the drum head, and packing material disposed between the ring structure and the adjacent portions of the drum head and shell, so as to bear against the opposing rivet heads and be re-strained thereby. Three claims.

# THE BOILER MAKER

## **AUGUST**, 1923

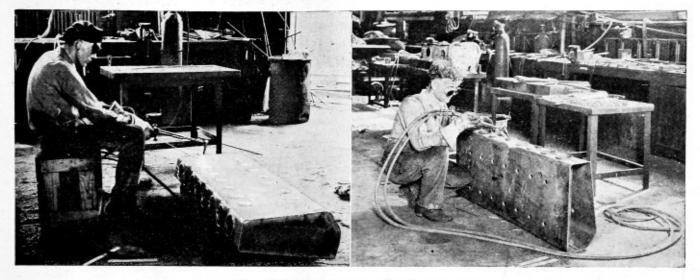

Fig. 1.-Welding Operations on Smoke Consumer

## Welding and Cutting Practice in the Boiler Shop

In the building of low pressure boilers, in pressure vessel construction, and in repair work, there are many acceptable applications of welding which speed up production and cut operating costs. The following article deals with a number of jobs, both welding and cutting, in which the oxy-acetylene process has been used with a high degree of success.

THE low pressure steel boiler industry offers many applications of the oxy-acetylene process in the manufacture, maintenance and ultimate disposition of its products. Welding and cutting is applied in various operations from the time the plates are brought into the shop, until the boiler is finished, it is applied at intervals throughout the life of a boiler for repairs and the worn out boiler is finally reduced to scrap with the cutting blowpipe.

When the sheets are received by the layerout they are often cut once to render them easier to handle. Such parts as dome saddles and throat sheets and openings such as manholes and clean out holes are easily cut at this stage of production to exact measure with a cutting blowpipe.

The sheets then leave the layerout for the shears and punches where unfortunately mistakes are sometimes made. A hole punched in a wrong place can, however, be welded in many cases and the sheets saved. A plate edge or angle iron damaged by the shears can be similarly reclaimed.

#### RECLAIMING CRACKED FLANGES

Boiler steel is of high quality, but flanges crack despite the utmost care both in flanging and in fitting up or assembling. Here again seemingly vital defects are easily corrected with the welding blowpipe. In fitting up, the dome of course must be driven down into the saddle, the mud ring into the water space. The old-fashioned heater bar, formerly used to help fit these heavy parts, is now being supplanted to a great extent by the oxy-acetylene blowpipe, which, by applying a maximum of quick heat to a small area, permits the parts to be fitted easily and properly. Staybolts are cut off to exact length for driving after they are inserted, and if, as occasionally occurs, the staybolt hole is made too large in tapping, instead of using an over-size bolt the hole is welded and another of correct size drilled and tapped.

Patching firebox sheets is a common application of oxyacetylene welding. Calked edges in riveted fireboxes deteriorate so that either new sheets must be installed at considerable expense or the edges reclaimed by welding, which costs very little.

#### FIRMS HAVE HAD LONG EXPERIENCE WITH WELDING

In Chicago a well-known boiler manufacturer has been using the oxy-acetylene process for over 10 years in the production of various types and sizes of boilers and exclusively in building low pressure steam and hot water boilers, water heaters and incinerators.

This boiler firm early recognized the economy and other features of oxy-acetylene welded construction. One of the first things he did before adapting the oxy-acetylene process to production was to construct entirely by welding a test section (shown in Fig. 5) which he turned over to a prominent physical testing laboratory to be tested in the severest manner possible. The results thoroughly convinced him that an oxy-acetylene welded joint was sufficiently strong and tight and he knew from available data that welding was more economical than riveted construction by a wide margin. The section was subjected to 3,500 pounds hydrostatic pressure, without giving the slightest indication of a leak or weakness.

#### Welded Steel Boilers

Quite as much has been accomplished by this manufacturer in the fabrication of welded steel boilers as other manufacturers have accomplished with all oxy-acetylene welded steel hot air furnaces. In both cases welded construction has made possible the elimination of riveted seams and cast iron sections and thus the objectionable features attendant to their use.

In comparison with cast iron sectional types the welded boiler has a uniform thickness of metal throughout—which is seldom found in cast iron sections. There are no parts liable to crack, or to collect soot and dirt on ledges or open

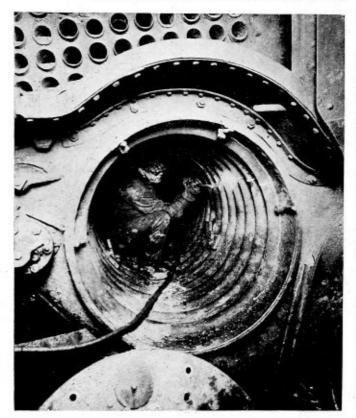

Fig 2.—Cutting out Burned Section of Scotch Marine Boiler Furnace

spaces between sections to result in low heat-efficiency. Leakage is the worst disadvantage of riveted seams in this type boiler. The oxy-acetylene welded boiler is like one solid piece of steel plate and as such leakproof. Welded construction also makes possible a larger amount of direct heating surface.

Not only has the oxy-acetylene process enabled this manufacturer to build a high class product, but it has reduced his production costs by simplifying methods and saving material. It has enabled him to build a boiler which saves his customers money on account of increased fuel economy and lower installation expense.

#### MINNESOTA FIRM UTILIZES PROCESS

A boiler and tank manufacturing company in Minnesota also produces upright and horizontal boilers, several types of storage and pressure tanks, and various specialties in which welding is extensively employed.

The company has adapted welding to the fabrication of

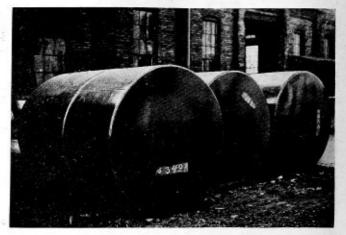

Fig. 3.—All Welded Oil and Liquid Storage Tanks of 1,000 Gallons Capacity

the firebox door of one type of upright boiler, with especially striking results. The old method was to flange the firebox plate outward to meet the outside plate of the boiler and then to lap and rivet the two together to form the firebox door.

The present method is to flange the firebox plate in the same way as formerly, but in addition to bend its edges around and over the outside plate. The bent-over edges of the firebox plate are then welded to the outside plate.

A trial boiler, made of 5/16 inch plate fabricated in this way, was tested under 150 pounds cold water pressure, and approved by the boiler inspectors in the district. There was not the slightest indication of leakage or weakness.

Besides increasing the durability of the firebox door, oxyacetylene welding has cut the cost of this joining operation at least 50 percent. The company now welds practically all the firebox doors in this way.

#### WATER TANK FABRICATION

High-pressure water tanks manufactured by this company are partly riveted and partly welded. Fig. 10 shows a tank of this type. In this tank the side seams are welded, and all the connections (consisting of 4 nipples varying from 1 inch to 3 inches in diameter) are joined to the body by welding

In another type the top plate is also welded to the side plate. The bottom plate is riveted instead of welded in order to permit removing the plate, if necessary to clean the inside of the tank or to repair the coils. This tank is subjected to a working pressure of 100 pounds and requires about 22 linear feet of welding. Another type of tank built in this

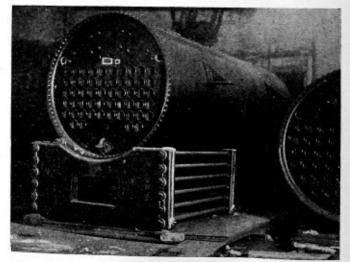

Fig. 4 .- Welding was Used Extensively in Building This Unit

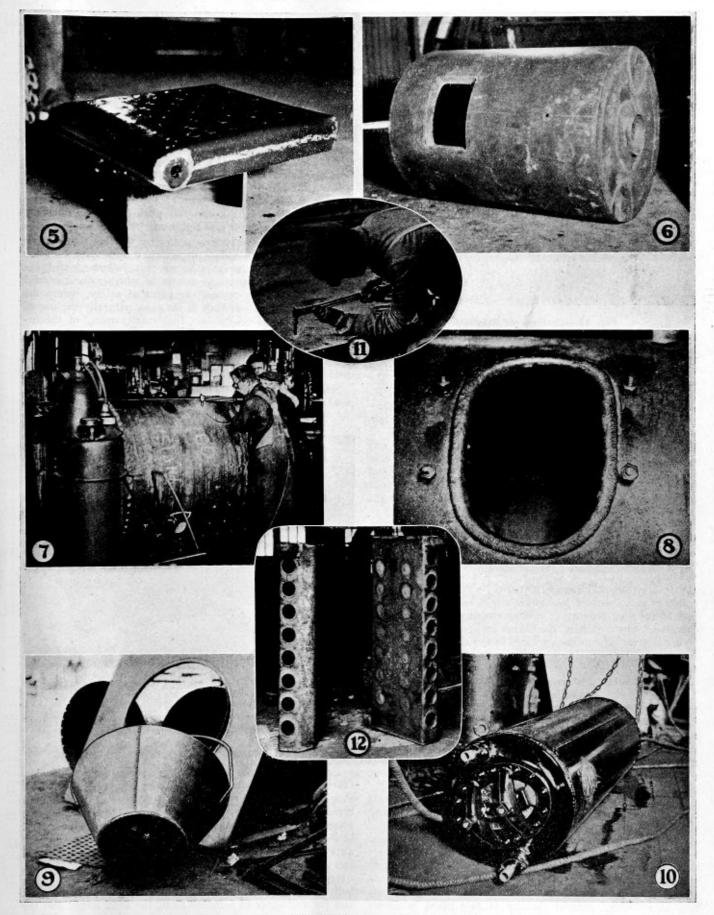

Fig. 5.—Welded Test Section. Fig. 6.—A Type of All Welded Low Pressure Boiler. Fig. 7.—Cutting the Fire Door. Fig. 8. —Close-up View of Welded Fire Door. Fig. 9.—All Welded Cooking Kettle. Fig. 10.—High Pressure Storage Tank. Fig. 11.—Cutting Boiler Plate. Fig. 12.—Welded Smoke Consumers.

Fig. 13 .- Cutting off Staybolts

plant has a capacity of 300 gallons, and requires approximately 16 linear feet of welding, including the side seams and connections.

#### MATERIALS USED

All storage tanks produced by this company are entirely oxy-acetylene welded. These tanks are adaptable to all liquid storage purposes. Some of them are 7 feet long and 5 feet in diameter, are built of 8-gage sheets, and have a capacity of 1,000 gallons. Each tank of this type has about 64 linear feet of welding, including side seam, a circular seam on the side-center, and two circular seams joining the top and bottom to the side plate.

The company manufactures several designs of oil tanks, divided into compartments, for use on wagons or trucks. These tanks are also all-welded, the compartment partitions as well as the tank body sheets being joined by oxy₇ acetylene welding.

Oxy-acetylene welding is extensively applied in the fabrication of various metal specialties, which form a considerable part of the total production of this company and other boiler concerns. One of these specialties is a cooking kettle for frying potato chips in deep grease, on a quantity basis. The kettle is 20 inches deep and 18 inches in diameter at the top and is made of ½-inch steel sheet. It is butt-welded throughout, and has about 140 linear inches of welding.

Pile caps and connections, made of 1½-inch steel, and used by contractors for capping and joining wood piles are also welded. Formerly these caps and connections were riveted, but the projecting rivet heads and the overlap of the joints were objectionable when sinking the piles into the ground, sometimes even splitting them. Welding eliminates these undesirable features and cuts in half the former cost of producing the caps and connections.

The oxy-acetylene cutting blowpipe is used largely by this company, especially for cutting odd-shaped metal pieces and for making openings in boilers and tanks.

This company has used the oxy-acetylene process for many years, and has kept comparative production cost records over considerable periods to determine the relative cost of welding and riveting, and of oxy-acetylene cutting and other methods of cutting. The result is that oxy-acetylene welding and cutting have become general practice at this plant, wherever they are adaptable. Oxy-acetylene welding or cutting is applied in some way on almost every product manufactured by the company.

#### WELDING WIDELY USED IN BOILER REPAIR WORK

Leaving the field of small boiler and tank work, the process has wide application in boiler repairs, both for cutting out sections of burned or corroded material that can be safely replaced by a welded patch and for building up metai that is still sufficiently strong to carry the working load, but does require a given thickness for proper fitting of parts.

As previously mentioned this latter use of welding is often effective where slight errors are made in the fabrication of plates that in no way endanger the structure but which can advantageously be corrected by the judicious use of welding. It is understood under the present status of the process that welding can only be used in high pressure boilers where the stress is carried by other parts of the structure than those which have been welded. In this work it is supplementary and adds both strength and tightness.

In the matter of salvaging plates by welding, however, it is unquestionably the shop inspector's duty and that of the state and district inspector to use his judgment and experience in such matters to determine whether the material has been weakened, beyond the point of safety, before the welding is applied. If such is the case, naturally the use of the process is not advisable. Incidentally many of the instances of pressure vessel failures on record, contributed to in violence by the failure of welded seams, might be traced to the careless use of the process in covering up defects or carelessness in workmanship.

Since the reputation and future of autogenous welding depend on the success of every single application, the workman-

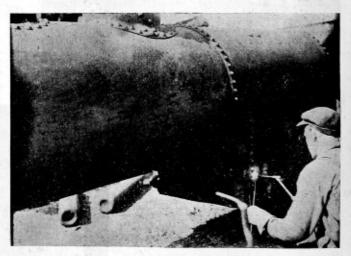

Fig. 14 .- Welding a Patch on a Firebox Type Boiler

ship must be above reproach and a torch never allowed in the hands of an unskilled or careless operator.

#### MARINE BOILER CONSTRUCTION AND REPAIR

For Scotch marine boiler work, welding has assumed a rather important part. Certain of the large shipyard boiler shops have been utilizing the process wherever possible in turning out boilers for sea service which oftentimes is very severe and proper maintenance is out of the question except at long intervals. In one case, for example, seams and stay nuts in the combustion chambers are welded up to a point 2 feet above the center line of the furnace. The inside butt straps are beveled down on the ends to the thickness of the boiler head flanges and welded across the ends at that point and for a distance of 6 inches along the head flange and the same distance along the butt straps from the flange. Where the shell plates butt together they are beveled and welded for a distance of 12 inches from each end. The saddle lugs, which are fitted with a ¹/₄-inch calking strip, as indicated before, are welded on the inside of the lugs to the shell.

Welded Seams

All seams of the combustion chambers in contact with flame are welded inside and out to protect the edges of the plates and insure against any possible leaks. This welding is carried to a point 2 feet above the center line of the furnaces. All screw stays up to a point 2 feet above the center line of the furnaces are fitted with special round collar nuts which are welded after being screwed on the stays.

# Work of the A. S. M. E. Boiler Code Committee

T^{HE} Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the secretary of the committee to all of the members of the committee. The interpretation, in the form of a reply is then prepared by the committee and passed upon at a regular meeting of the committee. This interpretation is later submitted to the council of the Society for approval, and then given publicity where it will reach the members of the industry who are interested.

Below are given the interpretations of the committee in Cases No. 412-417, inclusive, as formulated at the meeting of March 22, 1923, and approved by the council. In accordance with the committee's practice, the names of inquirers have been omitted.

CASE No. 412—Inquiry: Is it permissible, under the Code, to use on boilers, pressed-steel nozzles having the upper or bolting flange of the Vanstone joint construction, with the bolt-flange made of steel?

*Reply*: While the form of construction proposed for a boiler nozzle embodying the use of the Vanstone joint, as outlined, does not conflict with the requirements of the Code, provided the flange, dimensions, etc., meet the requirements of the Code for pipe flanges, it is the opinion of the Boiler Code Committee that a rigidly attached form of nozzle flange is preferable.

CASE No. 413—Inquiry: What is the permissible stress for screwed stays with ends riveted over less than 20 diameters in length, when such screwed stays are inserted in the sheets at an angle that is not truly radial in the case of curved plates, or in the case of flat plates is not normal to the plane of the plate?

*Reply*: It is impossible to formulate any logical requirement for a condition of that sort and it must be a matter of judgment. A revision of the Code has been proposed which reads as follows:

"All staybolts not normal to the stayed surface shall have not less than three engaging threads, of which at least one shall be a full thread."

The angularity in such case should not exceed 15 degrees to the stayed sheet. If the angularity is greater than 15 degrees it must be taken into account in calculating the permissible stress in the staybolt.

CASE No. 415—Inquiry: Where a boiler of the locomotive type is fitted with a form of removable drum, attached by bolted connection to the outlet nozzle, as is customary practice in the California oil fields, is it the intent of the Code that the requirements of Par. 194 shall apply to the construction of the drum, or can this construction be considered as a steam drum subject to the requirements of Par. 187?

Reply: It is the opinion of the Boiler Code Committee that the form of construction shown is not a boiler dome and therefore does not come under the requirements of Par. 194 of the Code, but must be considered as a steam boiler drum coming under the provisions of Pars. 187 and 188.

CASE No. 417—Inquiry: Is it the intent of the Code to require any particular design for suspension lugs to support horizontal-return-tubular boilers 78 inches or less in diameter?

Reply: It is the opinion of the committee that it was not the intent of the Code to require any particular design for suspension lugs to support horizontal return-tubular boilers 78 inches or less in diameter, but that any such lugs should conform to the requirements of Pars. 324 and 325 of the Code.

CASE No. 414—Inquiry: Is it permissible, in the case of the flue of an internally-fired boiler which is corrugated for about half of its length and the remainder plain, to calculate the thickness of the plain portion in accordance with Par. 239, assuming that the length of the plain portion is the distance from the center line of the rivets in the head to the beginning of the corrugations?

Reply: It is the opinion of the Committee that in the calculation of the thickness of the plain portion of such a furnace, Par. 239b should be used, taking for the length the distance from the face of the flange to the center of the first definite corrugation, and the thickness thus obtained shall be uniform throughout the entire length of the flue.

CASE No. 416-(In the hands of the Committee).

CASE No. 418—Inquiry: Is it permissible under the requirements of the Heating Boiler Section of the Code, to attach the safety valve to the pipe-header outlet connection of a type of cast-iron sectional heating boiler with sections designed too narrow to admit of a separate opening on any one of them for the safety valve?

*Reply*: If the design of the boiler is such that it is not possible to form the safety-valve openings directly on the boiler sections, it is the opinion of the Committee that the sections should be connected at two or more points to a manifold or header which will serve as a steam drum, and that it will be permissible to mount the safety valve on this manifold or header.

CASE No. 419-(In the hands of the Committee).

CASE No. 420—Inquiry: Is it permissible, under the requirements of the Boiler Code, to drive up a blister or blisters on a tube or tubes of a watertube boiler and reinforce them by depositing metal over the same by the autogenous process; or later when other blisters appear above or below the first reinforcement to again use the same process, increasing the length of the reinforcement; also to weld tubes lengthwise by the same process regardless of minimum or maximum length of weld for any thickness of tube and for any pressure without removing the tube from boiler or annealing the welding?

*Reply*: It is the opinion of the Committee that such reinforcement or welding of blisters or other defects in the tubes of watertube boilers would be analogous to the welding of cracks in shell plates subject to tensile strain which is prohibited under the Recommendations for Repairs by Welding in the Appendix of the 1918 Edition of the Code, page 127, third paragraph.

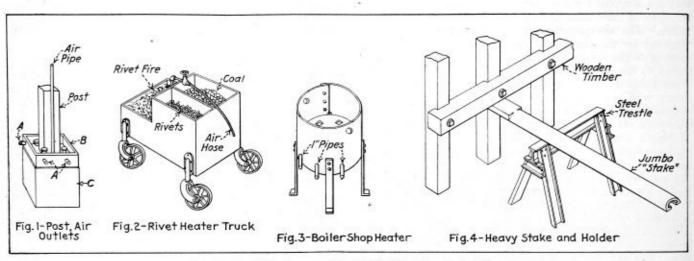

# Home-made Appliances for Boiler Shops

Structural Details of Equipment That Can Be Easily Assembled with Practical Applications of the Devices

#### By James F. Hobart

A FEW years ago I became interested in copying all the shop notices that were found in various shops visited, but about five or six years ago, the habit was abandoned. It was brought straight home to me that the average shop notice is not worth the paper it is printed on. Or, in other words, "not worth the powder to blow it to * * *!"

It was in the Big Four Railroad Boiler Shop at (Maple Grove) Indianapolis, Indiana, and I was reading a notice posted conspicuously beside a big grinding machine. Two supporting posts each set a couple of feet above the floor, upon square concrete piers. Around the top of each post pier or footing C, has been placed a frame B, as shown in Fig. 1. From four to six compressed air connections are to be found at each post as shown at A, A, A, the connections project through the frame just far enough for the men to connect on air hose to one or more as required. The air pipe as shown, comes down the post, and the valves which control the several air outlets, are all located inside of the frame, where they are well protected from accidental injury.

Easily Made Equipment That Will Help Out Production

pairs of stout goggles hung from a nail just under the notice, which was as follows:---

NOTICE—Any employee using this machine without goggles will be discharged. This will be enforced.

While I was reading, a man came and ground a tool on the machine, but he did not put on the goggles. In fact, he never even looked at them! The incident brought to mind the saying of an old shop foreman:—"It's easy to write notices, but it's a big job to enforce them."

Only a short time afterwards, I encountered another shop sign which killed all desire to add any more to my collection. This one was in a wash room where the foreman had evidently been unable to keep some of his men up to the required sanitary conditions. In despair, he had a sign made and posted to the effect that:—

"If you can't read, get to-----out of here!"

That notice capped the climax and the writer has added no more to his collection. It is all well and good to post notices on the shop bulletin board. Such posted notices are pretty sure to be read and if anything posted there is of interest to the workmen, they will heed the notice. But nine times out of ten, the effort is time, ink and paper wasted.

#### AIR-POSTS AND RIVET-TRUCKS

Here are a couple of kinks which were found in the boiler shop of the Lancaster (Pa.) Iron Works. They have a fine shop with concrete and dirt floors, and with the roofIn the same shop, I saw in use a rivet heater which was fastened upon a truck, or rather, what answered for one. Four big casters attached to the device, as pictured by Fig. 2, permitted the heater to be pushed almost anywhere, even where floor-room was quite limited.

The device was built of heavy tank steel and as shown it contains three compartments, one full of dirt, where the rivet fire is kindled and kept going by a blast from the air-hose on top of the heater. The two other compartments are—a large one for coal and a smaller one for rivets. This makes the appliance pretty well self contained. Mounted on the big casters, it can be moved easily and quickly, and even spun around "in its tracks" with little trouble or loss of time.

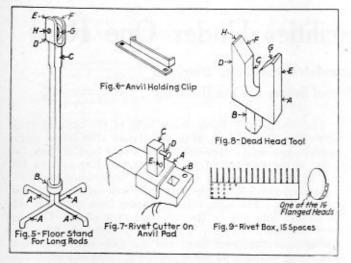

I have not shown the manner in which that rivet-truck was put together for I wanted you to have an open mind when you make one for your shop. Then you can, if you wish, flange and rivet the plates together. Or, you can rivet each one to corner angles. But, before you select either of the above noted ways, just consider making up the truck with an oxy-acetylene welding torch, thereby making a truck as smooth and clean-looking as the one shown by Fig. 2.

It is not very seasonable, just at this time of the year, to lug in a shop heater, but here's one which is so mighty simple that I wish you would take a look at it as pictured by Fig. 3. We wont start a fire in it just yet, but give it the "once over" and note that it is made from a bit of tank steel, or a piece of plate from some old boiler. There are four legs riveted on, holes made for three pieces of one-inch pipe, and a loosely fitting bottom plate has three rough holes in it. The holes in the sides, near the upper edge, are for attaching hooks of a chain suspended from the shop crane. In this manner, the heater may be quickly moved from place to place even while the fire therein is burning briskly.

When a new fire is to be lighted, pulling out the three pieces of pipe will dump the old fire and leave the heater clear and clean. Replace the short bits of pipe, drop the perforated bottom plate in place and the heater is ready for the new fire. When the fire burns too fiercely—something that hardly ever happens in a chilly boiler shop—a bit of steel plate on top of the heater controls the fire to a nicety and is much appreciated at noontime by the workmen, for heating their dinner-bucket coffee-cans.

### BOILER-SHOP STAKE-HOLDER

A big "stake" similar to the kind used by tinners and sheet metal workers, is a mighty handy thing to have in a boiler shop, even if it is necessary to improvise a stake by making a hitch with the shop crane around a length of railroad iron, lifting it level, with the far end on a barrel and then using the end of the rail as a stake where it overhangs the crane

Anvil Attachments and Other Convenient Devices

fastening. That scheme works well, all right, but it is not quite as handy as a stake arrangement in use in the "T. & P." shops, New Orleans, La.

Such a "Jumbo" stake and a permanent built-in stakeholder is shown in Fig. 4. This stake is a huge affair ten feet long, or so, made like the one used by tinners, only larger. A bit of railroad iron, a piece of shaft or even a narrow floor-plate can usually be found doing duty as a stake, the permanent fastening therefor, permitting the use of almost any kind of a stake, from a bit of timber to the fine stake shown by Fig. 4. This engraving shows one end of the stake resting underneath a timber which has been permanently framed into the timber work of the building. The free or work end of the stake hangs over a stout steel trestle or "horse," made expressly for the purpose, with a stiff I-beam backbone, capable of supporting almost any load likely to be placed upon the stake. Do not make the mistake of placing a steel beam in the building to hold down the back end of a stake, as shown. Steel used thus is too noisy, and even a boiler maker sometimes finds it pleasanter to his ears with a bit of board interposed between the trestle and the stake-it makes far less noise, thus.

#### A TROLLEY FLOOR STAND

The New Orleans "T. & P." shops have also the appliances shown by Figs. 5, 6, 7 and 8. When long rods have to be worked, either in the forge shop or while being threaded and cut off, an appliance which will support the far end of the long rod is often badly needed. Such a rig, and a mighty neat one too, is shown by Fig. 5. It was made from four lengths of round black steel, the ends A, A, turned out and down four feet, after the other ends of the four rods had been securely fastened together by a shrunkon band B, and then welded solid into a head C, which was later split as shown at D, and forged into jaws E and F to receive sheave G, which in turn was fastened by pin H.

No attempt was made to have this stand adjustable in height. It was made just high enough for the work it was to do, and fixed that way, for good. The top ends of jaws E and F were rounded off, and also beveled sidewise so that should a rod happen to strike on top of the jaws, it would slide off upon the sheave, rather than off the stand altogether.

#### Some ANVIL TOOLS

Several rigs and jigs for use on anvils in the boiler shop of this railroad are shown in Figs. 6, 7 and 8. A stout bit of boiler plate, two bits, in fact, were sheared long and narrow as shown by Fig. 6, then flanged lengthwise in the middle, square spike holes punched as shown, then the ends were bent inward as shown, and hammered snugly down against the base of a big anvil. A strip was placed at either end of the anvil and, after having been forged snugly against it, railroad spikes were driven through the square holes in both straps, fastening them and the anvil securely to the anvil block.

The value of these clips became apparent whenever the anvil happened to get upset, as the block remained right in place, where it belonged. Also, when the anvil was moved around the shop by the overhead crane, it never parted company with the block, but a hitch from the crane-chain, took both along together.

#### RIVET-CUTTER AND ANVIL "DOLLY"

A four-inch square bit of steel six or seven inches long was shouldered at one end and riveted into or welded upon a strip of heavy boiler plate as shown at A and C, Fig. 7. Then the ends of the plate strip were bent downward so as to slide easily along on top of anvil B.

Holes of several sizes were drilled in the sides of the steel post as shown at D and E. The top of the post formed a dandy place for driving small rivets in flat work and when a rivet was too long, it could be inserted as shown at D, in the proper size of hole, and a stroke from a sledge, against a handled cold chisel, quickly cut the rivet off flush with side of the post. The smith also found this device handy when forging small articles and needed a square corner sharper than could be found on the shop anvil.

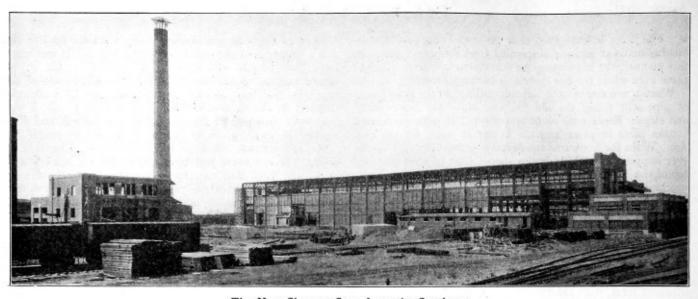

#### "BUCK-HORN" AND BENDING TOOL

A very handy anvil tool of the "deadhead" class was made by slotting a stout piece of tool steel as shown by Fig. 8 at C. Then the lower end of the steel was shouldered down to fit the hardy-hole of the anvil. Later, the sides of the tool, D and E, were beyeled back as shown at F and G, until only a narrow flat end was left on each side, as shown at H.

This tool found a great variety of uses. When small rods or straps had to be bent, one of them would be placed between jaws D and E, in slot C, and by "taking a pry" on end of the piece and properly reinforcing with sundry hammer blows, the piece would be bent easily and quickly, without having to go to a vise with the work.

#### STEEL RIVET BOXES

Down in Memphis, Tennessee, in the I. C. boiler shop, I saw a mighty convenient receptacle for keeping rivets safe, and handy at all times. What is more, all kinds of rivets used in the shop were kept in a couple of these boxes which, as shown by Fig. 9, were made from boiler plate and contained from eleven to fifteen compartments each.

The New Shop as Seen from the Southeast

# Repair Shop Has All Facilities Under One Roof

## New "Katy" Plant Accommodates Erecting, Machine Tools, Boiler and Tank Work and Stores in One Building

'HE comprehensive program for the improvement of facilities for the handling and repairing of locomotives which has been carried out on the Missouri-Kansas-Texas, under the receivership recently terminated, includes the construction of a locomotive repair shop at Bellmead terminal, Waco, Tex., at a cost of about \$1,700,000, which is designed for the conduct of all classes of heavy locomotive repairs. In addition to the large repair shop building, which is of particular interest because it houses all the necessary facilities for the conduct of locomotive and boiler repairs under one roof, the improvement includes a number of auxiliary facilities, of which the most important is a large modern power house. The new facilities have been designed to fit into the existing layout at Bellmead, making such rearrangements as were found necessary, including certain changes in track locations. It was necessary, however, to make some additions to the land area devoted to terminal purposes at this point.

The present construction is planned for heavy repairs to 16 to 20 locomotives per month and, while the shop is designed primarily with a view to economical operation under present conditions, consideration was also being given to its adaptation to a plan for future development with a minimum expense for rearranging buildings and tracks.

#### BOILER SHOP ARRANGEMENT

The main portion of the shop building is 475 feet long by 151 feet wide, measured inside the walls, and is subdivided into 19 transverse bays 25 feet wide, and 2 aisles or longitudinal bays, 80 feet and 71 feet wide respectively. A second aisle 71 feet wide forms a wing for a length of 8 bays or 200 feet along the north side of the building at the west end, while at the east end of the building is another wing, 152 feet, by 50 feet projecting south from the south side of the building for a distance of 74 feet 2¼ inches. Also along the south side of the building are two smaller wings, one 25 feet by 150 feet and the other 25 feet square, while another small wing, 27 feet by 58 feet 8 inches projects from the north side of the building. The 80-foot aisle in the main body of the building comprises the erecting shop, while the 71-foot aisle serves as the machine tool shop. However, the first four bays of these two aisles at the west end of the building, covering an area 100 feet by 151 feet, will be utilized as a boiler shop while the remaining 375 feet of these two aisles will serve as the locomotive shop. The large wing projecting from the north side of the building will be the tank and plate shop. The east bay, which is a two-story structure, will house the stores department on the lower floor, and the shop office and manufacturing toolroom on the second floor. The two small onestory bays along the south end of the building will house locker and toilet rooms for white and colored employees and two fan rooms, while the small wing on the north side of the building will be used as a distributing toolroom and foreman's office.

The building is of steel frame construction throughout with the major portion conforming to the prevailing standards of industrial building construction. The erecting aisle has a clear height of 53 feet 1 inch to under-clearance of the roof trusses which are supported on columns conforming to the 25-foot transverse bay arrangement and designed to support the roof trusses and two crane runways, the upper one for a 180-ton crane to handle locomotives and the lower one for a 15-ton crane to be used in handling lighter parts. As it is believed that the 180-ton crane can readily handle all movements of locomotives to and from the various pit tracks, it has been deemed unnecessary to provide a transfer table. Each of the 15 bays in that portion of the erecting aisle to be used for the locomotive erecting shop is to be equipped with a track and track pit each track extending a distance of eight feet into the machine tool aisle.

The two 71-foot aisles are of duplicate construction except that the one used for the tank and plate shop does not extend the full length of the building. The underside of the roof trusses in these two aisles is 35 feet 7 inches above the floor, and each is equipped with a crane runway with top of rail 26 feet 4 inches above the floor. The crane in the machinery aisle is to be of 15 tons capacity, while that in the tank and plate shop aisle is of 40 tons capacity. The roof trusses in each case are of rectangular outline except that a single saw tooth is superimposed on each with its top extending to a height of 16 feet above the general level of the roof and providing a window area having a vertical height of about 12 feet.

An interesting detail in connection with the efficient operation of the machine shop is to be found in the extension of the crane runway for the machine tool shop for a distance of 75 feet beyond the east end of the building, or over a casting platform and the tracks adjoining it so that the crane can be used for unloading castings or in transporting them from cars or the platform to any of the machine tools in the shop.

The shop floor is of reinforced concrete, with a mastic surface, while the roof consists of cement tile, covered with composition roofing. The walls of the building are almost entirely glass. Along the two sides of the main shop structure, the glass extends for the full width between the faces of columns which are exposed at the outside of the building. The two ends of the shop are also largely of glass, except that ornamental treatment is provided in the form of brick pilasters, and brick facing in the plane of the trusses. The brick work is ornamented with concrete belt courses and copings. The glass areas in the smaller wings and in the portion of the building used by the store department and the manWaco station of the Texas Power and Light Company.

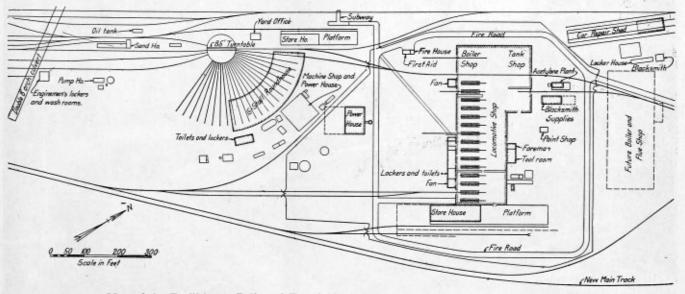

Among minor outbuildings are a supply building for the blacksmith and boiler shops, a paint shop, an oxy-acetylene plant, a first-aid room, and a fire engine and hose house. The work under way also includes a brick lavatory and locker building for roundhouse employees. A concrete subway 8 feet by 8 feet, 355 feet long has been constructed under the yard.

The preparation of the site involved 140,000 cubic yards of grading and the relocation of a mile of main track. The work includes about 3,300 cubic yards of reinforced concrete in culverts, subway and foundations and 2,000 tons of steel.

## **Comparison of Tool Steels**

A N important method of comparing tool steels is known as the lathe breakdown test. In this test the tool is used for cutting into a steel of definite composition, and works at a known speed and rate of cutting until it is worn out. A report on such tests has been issued by the Bureau of Standards telling of the results of such tests on various kinds of modern tool steels and discussing the limitations of this method when applied to the purchase of steel. The conclusions drawn are summarized as follows:

1. Breakdown tests are not satisfactory as a basis for the purchase of high-speed tool steels.

Map of the Facilities at Bellmead Terminal. New Structures Indicated by Heavy Lines

 Competitive comparisons of brands having nearly similar performance is not justified, owing to the qualitative nature of this type of test; but relatively large differences may be determined.

the entire building is set in steel sash. The building is heated throughout by a forced draft hot air system from the two fan rooms mentioned above where air driven through steam coil heating units is transmitted through concrete ducts under the floor to outlets distributed

ufacturing tool room is also large but with considerable area

in brick pilasters and concrete trim. All glass throughout

throughout the building. The brick and steel power house is located between the shop and roundhouse. The present construction is designed for the use of oil as fuel, with provision for the installation of coal and ash handling facilities when required. The reinforced concrete chimney is 8 feet in diameter, and 177 feet high. The power installation includes 328 horsepower watertube boilers and appurtenances, two air compressors of 2,000 and 500 cubic feet capacity, and duplicate fire pumps.

The shop is completely equipped with new machinery, driven by electric power with individual motors. The circuits are generally carried in conduits under the floor. A circuit with self-registering apparatus is provided for checking machine performances. Electric power is furnished from the 3. Certain severe breakdown tests were made with roughing tools on three percent nickel steel forgings, and in them high frictional temperatures were produced. In these it was found that the performance of commercial low tungsten, high vanadium and cobalt steels was superior to that of the high tungsten, low vanadium type of and special steels containing about one-fourth percent uranium and three-fourths per cent of molybdenum.

4. Modification of the test conditions, including small changes in tool angles, but principally changes in cutting speed, had a more marked effect on the performance of steels containing cobalt or special elements, such as uranium or molybdenum than it did on that of the basic types.

5. The high tungsten steels showed relatively poor endurance under severe working conditions, but did much better in more moderate tests. The latter were made on the same test log and with equal cutting speed and depth of cut, but with reduced feed. The frictional temperatures were not so high.

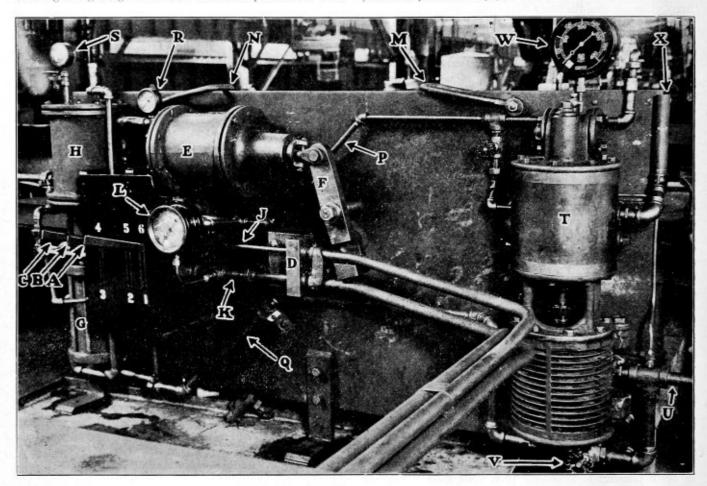

6. Hardness determinations and examinations of fractures indicate that the various types of commercial high speed steel show differences in behavior under heat treatment and in physical properties which are of importance under moderate working conditions and might counterbalance slight advantages in performance.

# **Device for Testing Superheater Units and Air Reservoirs**

Speed in Operating and Accuracy and Severity of Testing, Features of New Device

ONE of the most simple and efficient devices yet developed for testing superheater units and air reservoirs is shown below. It was designed and constructed for use in the Readville shops of the New York, New Haven & Hartford.

As shown, the operating mechanism is mounted on a large steel back plate 1 inch thick, supported on the bottom by three right-angle legs with holes drilled to provide for boltby means of a piston rod. The piston in H is operated by shop air pressure at 80 pounds from a one-half inch pipe, the pressure being shown by gage S. The unit is filled and tested through pipe J, being blown out through pipe K which is connected through a suitable valve to the exhaust, not shown. The test pressure on the unit is indicated by gage L, being between 400 and 500 pounds. Shop air pressure at 80 pounds is provided in pipe P, the connections being such that

A Compact and Efficient Device for Testing Superheater Units at the Readville Shops of the New York, New Haven & Hartford

ing to the floor. The rugged design of the testing device throughout is evident from the illustration. Moreover it is a compact unit which can be readily moved to the most convenient place in the shop by means of a crane and chain hooks attached to the hangers M and N. At the time of taking the photograph the tester was not in its final location and it has since been moved to the erecting shop where superheater units can be handled to and from the device with the minimum effort.

Referring to the illustration, a superheater unit is shown applied to two false seats in the substantial angle block Drigidly bolted to the back-plate. In testing, the unit is held with a heavy pressure against block D by means of lever F, pivoted as shown and operated from brake cylinder E. The final test pressure on the unit is obtained by hydraulic pressure from cylinder G direct-connected to brake cylinder H this pressure is shown by gage R. City water at a pressure of 40 to 50 pounds is provided to pipe Q and used for filling the units and hydraulic cylinder G.

This tester is operated by means of three levers A, B and C, each of which has two positions and is interlocked with two three-way valves. Three levers are required, for the reason that there are three main pipe connections, namely city water, high pressure water and air required in blowing out units. The arrangement of the interlocking levers to the six valves is extremely ingenious and foolproof, making it impossible to perform the various operations out of their proper order. Moving handle A to position I supplies air to brake cylinder E, clamping the unit quickly and with a heavy pressure which practically eliminates all chance of leakage at the two joints. Handle B is moved to position 2 allowing water at street pressure to fill the unit and cylinder G. Moving handle C to position 3 shifts off the water supply and admits air on top of the piston in cylinder H applying hydraulic pressure to the unit. Moving handle C back to position 4 exhausts the air in cylinder H and closes the connection from cylinder G to the unit. The unit is opened to the atmosphere and water and scale blown out by shop air pressure when handle B is moved to position 5. Moving handle A to position 6shuts off air pressure to the unit and releases the air in cylinder E, also releasing the unit.

All of the above operations take far longer to describe than to perform. In fact, a unit can be applied on this device, tested and released in a fraction of a minute. Not only is the operation speeded up but the test is much more thorough and severe than that ordinarily accorded superheater units. Cylinder G is bushed so that a pressure of 400 to 500 pounds is obtained quickly showing up any defects which exist. This allows defects to be corrected before the units are reapplied and perhaps cause service failures.

#### TESTING RESERVOIRS

Air reservoirs are tested by means of the Westinghouse  $9\frac{1}{2}$ -inch air compressor T which is bushed on the air end to boost the shop pressure to at least 225 pounds, at which the reservoirs are tested. Pipe U is connected to the reservoir (not shown in the illustration), and in operation valve V is opened allowing water to practically fill the tank. Valve V is then closed and the air compressor started increasing the pressure on the reservoir to 225 pounds when the standard hammer test is given. The test pressure is indicated by gage W, connected by a copper pipe to the tee at the air discharge as shown. Pipe X is the exhaust from the air compressor.

## Making a Long Radius Arc

#### **By Phil Nesser**

OFTENTIMES we come across a job in the layout of boilers or steel work, where it is necessary to lay out an arc of such radius that our tools will not reach the center of the arc; for this, the writer wishes to suggest the following method:

Suppose we start with a small circle, reasoning that in Fig. 1 the dimension A multiplied by the dimension B will equal the square of the dimension C. Expressing this in a formula, we have C squared equal to A times B or  $C^2 = AB$ . And C is the square root of the product of A times B.

The dimension A in Fig. 1 is the height of the segment of the arc, of which two times C is the length of the chord, and A plus B equals the diameter of the circle. The radius would then be the sum of A plus B divided by two.

In large arcs the dimension D, Fig. 1, is so near onefourth of the dimension A that it can be used as such for all practical work and give as close results as we are able to measure without getting into hundredths of an inch, that is, if the arc is over ten feet radius. For less than that we could use the trammels. Also we must not take too much of the circle into the arc, say, not over 30 degrees on the arc, and the method here given will work out.

Considering that the diameter is twice the radius of the circle, then the radius is always the sum of A plus B divided by two. Assume that we have to draw an arc of which the radius is to be 200 inches, the diameter would be 400 inches. If the dimension A equals one inch, B must then be 400 minus one inch or B is 399 inches. Considering that C in Fig. 1 is the square root of the product of A times B, we can see that the length of half the chord would be the square root of 399 inches.

Turning our attention to Fig. 2, the dimensions are marked, one inch in place of the letter A as in Fig. 1, and 399 inches

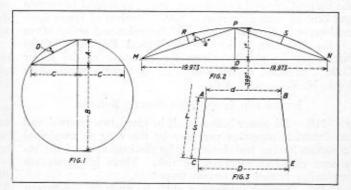

for the dimension B and the product of A times B would be 399 inches.

Extracting the square root of 399 need not scare anyone, for we have books with these things all worked out, and we have only to find the table of squares and square roots of numbers that are printed in most all pocket memorandas, or books of mechanics' tables. Several such books are published by the large steel companies and can be secured by corresponding with them, or from any book store.

The square root of 399 is 19.973. This is substituted for C in Fig. 1, and marked upon Fig. 2 as the length of half the chord of the arc.

To construct Fig. 2, draw a line of indefinite length as M-N. At any point, as O, draw the perpendicular line O-P, which is to be one inch in length. From the point O measure each way 19.973 inches, locating points M and N. This locates M, P and N. Then draw a line from M to P. Bisecting this with a perpendicular line one-quarter inch long, locate point R. This is repeated on the line N-P, locating point S. Having located points M, R, P, S and N, we can trace the arc through these points.

If more points are desired, we could draw chords again connecting each of the located points and setting off from

Long Radius Arc Details

the center of each one-sixteenth of an inch for the heights of the segments of each newly formed chord. The next such subdivision would give only one sixty-fourth of an inch for the heights of the segments of newly formed chords, etc., for each time the chord is divided in two parts, the segment diminishes in height one-fourth.

Recalling a case where this would be of use, Fig. 3 shows the side elevation of a tapered cylinder. AB is the small diameter, CE is the large diameter. To lay out such cylinder we may not have a chance to use the trammels on account of the extreme length of the dimension L, which is the distance, measured along the slant, from the point C to where the sloping sides would meet, if continued to a point. The slant height S, Fig. 3, multiplied by the large diameter, and this divided by the difference between the two diameters, gives the length of the long radius that it takes to lay out the pattern of the taper cylinder. This, expressed in a formula, is the product of S times D divided by D minus d equals

L, or 
$$L = \frac{S \times D}{D - d}$$
, in which S is the slant height of any

tapered pipe, D the large diameter, d the small diameter and L the length of the long radius in the pattern. As the method of making the pattern has been described so many times before and as the only part the writer wishes to bring out is the method of making a long arc, we will omit the making of the pattern of the tapered cylinder in this article. Suppose we had to make a tapered cylinder with the large end 20 inches diameter, the small end 19 inches diameter and the slant height 10 inches. Substituting these dimensions

公道 [] - [] - []

for the letters in the above formula, we have  $L = \frac{10 \times 20}{(20 - 19)}$ 

and L is found to be 200 inches. The work given in Fig. 2 will explain how to make the arc to get the large end, and by drawing a concentric line 10 inches away toward the center of the arc, taking the lengths of the circumference upon

each arc for each respective end we could lay out such a cylinder without making it up to full size outlines, and save the time of making such outlines.

To make the arc after locating points as explained in Fig. 2, we take a steel straight edge about 2 inches wide set on edge and bend it flatways until it passes through the points, taking 3 or 4 points at a time.

## **Rules for Inspecting Power Boilers**

### Methods for Making Internal and External Inspections to Determine Fitness of Boilers for Service

THE following paragraphs constitute a section of the preliminary report of the A.S.M.E. sub-committee on the operation and care of power boilers—under the Boiler Code Committee. The rules apply only to steam boiler construction in compliance with Part 1, Section 1 of the Boiler Code and to those not subject to federal inspection and control, including marine boilers, boilers of steam locomotives, etc. Complete details of the rules and action taken by the American Society of Mechanical Engineers in the matter can be obtained from the Secretary of the Boiler Code Committee, C. W. Obert, 29 West 39th street, New York, N. Y.

#### RULES FOR INSPECTING POWER BOILERS

C-210. All power boilers shall be given two external and one internal inspection per year by the state or municipal inspectors having jurisdiction or by the inspectors of the insurance company carrying the risk. These inspectors are hereinafter termed authorized inspectors.

C-211. Similar inspections shall be made by the person responsible for the boiler plant as a whole, who is hereinafter termed the plant inspector. Such inspections shall be supplementary to and in no wise considered as supplanting or superseding the inspections made by authorized inspectors. Such inspections shall be made in accordance with the following rules:

C-212. Between periodical inspections by authorized inspectors, the plant inspector shall closely observe the operation and condition of the boilers and shall report immediately to the proper authorities any serious defects, doubtful conditions or unusual occurrences.

C-213. An external inspection shall comprehend the superficial examination of the boiler, its appurtenances and connections and does not necessarily require that the boiler be off the line. It is a form of examination to check up care and management mainly.

C-214. The internal inspection of the boiler shall be a comprehensive and thorough examination in every detail, embracing particularly the determination of the suitability of the boiler for load and pressure carried, strength of its parts, possible deterioration in service and advisability of its continuance under the pressure carried previously to inspection.

C-215. No particular preparation shall be necessary for an external inspection other than giving the plant inspector convenient access to the boiler and its connections.

C-216. The internal inspection shall call for somewhat extensive preparation, mainly the proper cooling and opening up the boiler together with a thorough cleaning of the boiler, including setting.

C-217. The cooling of the boiler shall be done cautiously so as not to put undue stress on the heated surfaces and setting. The damper shall be opened wide and the ash pit doors opened, allowing circulation of air in the usual way. The fire doors shall remain closed until after boiler is cooled.

C-218. During the cooling process the large doors in the boiler front shall be kept closed in order to prevent rapid cooling of tube ends.

C-219. After the furnace and lining have become well cooled the fire doors may be opened as well as the clean-out door at the rear preparatory to sweeping out the accumulated ash and soot.

C-220. The walls, baffles, tubes and shell shall be thoroughly swept down and the ash and soot removed to give the plant inspector opportunity to examine the parts closely and to eliminate danger from hot contact.

C-221. The tubes shall be well dusted and cleaned with steam soot blowers before the cooling operation has commenced. Steam shall not be used to clean tubes of a cold boiler as the moisture cements the soot and ash into a hard mass difficult to remove.

C-222. When boiler and setting are thoroughly cooled the blow-off valve shall be opened and the water removed. Then the manhole and handhole covers shall be removed to allow circulation of air.

C-223. The inside of shell, drums and tubes shall then be washed down thoroughly to remove mud, loose scale, etc. The washing operation shall be conducted from above as far as possible to carry the material downward to blow-off or lower handholes.

C-224. Before the washing operation is commenced a wire gauze screen of cylindrical form shall be inserted in each blow-off opening, projecting up into the boiler several inches, whose function is to prevent loose pieces of scale from entering and clogging the blow-off pipe.

C-225. The plant inspector shall have available the data on the boiler, dimensions, age, particulars as to previous defects noted, if any, and shall proceed to check up the pressure carrying capacity of boiler subject to conditions found during complete inspection.

#### EXTERNAL INSPECTION

C-226. The plant inspector shall examine the boiler for level, noting whether or not there has been any tendency to settlement, especially the level of the top tubes in horizontal return tubular boilers. He shall see that proper provision is made for expansion toward the back of boiler.

C-227. Examination shall then be made of the feed connection to see that it is clear and in good working condition.

C-228. Examination shall be made for evidences of corrosion on exterior of shell from rain coming down stack and leaking roofs, valves and pipes.

C-229. Inspection shall be made to see if there is any leakage of flame on dry sheets, particularly at the back arch of return tubular boilers, which should be entirely clear of rear tube sheet with sheet metal or asbestos rope covering gap. Tie rods and buck stays shall be examined for condition and possible shifting from place

possible shifting from place. C-230. Where the boiler top is covered with brick or other material, it should be removed sufficiently to allow proper inspection of riveted joints.

C-231. The plant inspector should note proximity of overhead shafts or any machinery which might drop down on or strike boiler in case of accident.

C-232. The plant inspector should note the presence of lumber, or other material piled on boiler or setting for purposes of drying or storage and which may endanger the setting or the safety and accessibility of the apparatus.

C-233. A careful examination shall be made of the safety valve, its connection to the boiler, escape pipe, its drip, supports, etc. He shall also test the safety valve by hand.

C-234. The water glass, gage cocks, water column connections and blow-offs shall be tested to see if the connections are free. Boiler pressure gages and master gages shall be tested.

#### FURNACE AND PARTS EXPOSED TO FIRE

C-235. The plant inspector shall go into the furnace for the examination of the exterior of the tubes, shell, brickwork, etc.

C-236. He shall examine carefully for bulges over the fire, leaky rivets, loose rivets, rivets out of alignment, corrosion, wasting away of plates, cracks, etc.

C-237. The plant inspector shall scrape the shell and tap it thoroughly with hammer to detect thin places. He shall check thickness of plates with steel scale measurement. He shall examine joints and sheets over the fire particularly for possible fire cracks.

C-238. The plant inspector shall examine the setting for cracks, settlement and loose brick which may lean against the boiler. Where brickwork is used as insulation of steel supporting members it shall be examined to see that it is in good condition and that the air space, if any, is maintained. The furnace lining shall be examined for spauling, cracking and settlement. In vertical boilers, bridge walls shall be inspected to see that the mud drum is properly protected. The plant inspector shall examine baffle and check walls particularly for holes which may permit flaming through.

C-239. The blow-off connection should be examined carefully for corrosion and weakness where it screws into the boiler. The protecting cover of brick or tile should be intact and not interfere in any way with the expansion of the boiler or pipe.

C-240. Particular attention shall be given the tube ends and tube sheets in the case of horizontal return tubular boilers, the plant inspector noting any corrosion of the sheets, signs of leaking tubes, excessive thinning of the tubes from repeated rollings, and any cracks in the tube ends.

C-241. The plant inspector shall note any tendency to corrosion from leakage of manhole and handholes under tubes in tube sheets of return tubular boilers.

#### INTERNAL INSPECTION

C-242. The plant inspector shall enter the drums of the boiler to make personal examination of conditions, first making sure that they have been properly ventilated and that there is no inflammable gas present from oil used to coat the boiler as the water level is lowered.

C-243. Before entering the shell or drum the plant inspector shall see that the blow-off valve, the main steam valve and other valves are locked and the keys in his possession.

C-244. Careful examination of the interior of the boiler shall be made for pitting, corrosion, scale and thin places in shell. The upper half of drums in the steam space shall be examined particularly for signs of grease and oil.

C-245. The interior of the tubes should be examined for

scale and deposits and the space between the tubes in case of return tubular boiler made visible by lowering candle orsmall light between them for the purpose of making surethat there is no restriction of the circulation.

C-246. The location of the feed discharge and condition of the trough under it shall be noted. Dry pipes shall be examined to see that their openings and perforations are free from deposits. All interior fittings shall be examined for loose connections.

C-247. The interior face of the riveted joints shall be examined for condition of riveting, thinness of metal, corrosion, cracks, etc. The plant inspector shall note wasting away and cracking of stays and braces. Particular note shall be made of any welded stays or braces.

C-248. The fusible plug, if used, shall be examined, the top scraped to expose the condition of the metal and the plug renewed in case it has seen a year of service. The surface of the boiler about the plug shall also be scraped.

#### INSPECTION OF APPURTENANCES AND SUPPORTS

C-249. An examination of the condition of the main header and its connections to boiler shall be made to ascertain that it is properly supported, that due allowance is made for expansion without throwing strains on the boiler, that the non-return stop-valves are in good working condition and so placed that there is no pocket in the connection to hold water.

C-250. The plant inspector shall note the position of the steam gage, gage cocks, ascertain that the pipes leading to the water column, and water glass are level, and by leveling across the top row of tubes or from the position of the fusible plug check the position of the water glass.

C-251. Check pipe line and all exterior supports to see that the proper tension and alinement is maintained. Where boiler foundations are independent of building foundations, joints on the steam and feed connections shall be disconnected once a year to check possible settlements.

C-252. In addition to the above inspections, the plant inspector shall observe the condition of the interior of boiler at least once in every three months or at more frequent intervals if the boiler is opened for cleaning or repairs. Each time the boiler is removed from service, the plant inspector shall look for signs of defects where observations cannot be taken while the boiler is in operation.

C-253. A record of each inspection shall be kept in a uniform manner so that any change of condition can be definitely compared especially with reference to thickness of scale, corrosion, cracks, etc.

#### CARE AND MANAGEMENT

C-254. The plant inspector shall note particularly any evidences of carelessness in the care and management of the boiler and its appurtenances.

C-255. The plant inspector shall demand immediate remedy of any unsafe conditions or undesirable practices he may uncover and shall report fully on the results of his inspection to the owners of the boiler plant, promptly.

C-256. The plant inspector shall be furnished a copy of all reports of inspections made by authorized inspectors and shall see that all recommendations in such reports are promptly and carefully carried to completion.

ENGINEERING SCHOLARSHIPS.—The Mechanical Division of the American Railway Association has four scholarships at Stevens Institute of Technology, Hoboken, N. J., two of which are now vacant. These scholarships are available for the sons of members of the division and cover the regular tuition charges for a four-year course, leading to the degree of Mechanical Engineer (M. E.). The course offered also includes instruction in electrical, civil and other branches of engineering.

## Boiler Inspecting in South Africa

## Details of Boiler Supervision and Qualifications and Experiences of Inspectors in a Strange Land

#### By George Cecil

LTHOUGH the activities of the boiler inspector in South Africa are restricted by the lack of manufacturing concerns, the railways and the docks keep the small corps more or less busy. True, in an area of over a million square miles there are but ten thousand miles of railways; but the docks with their shipbuilding and repairing yards, and innumerable cranes, find employment for the boiler inspector, as also do the mines. The man whose work pins him down to Capetown or Port Elizabeth, seldom has time to be idle, for apart from the actual inspecting, many complicated returns must be kept. He is "administered" by the government, his duties being associated with endless red tape procedure. The appointment certainly is worth having; but it is not without vexatious worries. Those who pass the necessary qualifying examination, though assured of an adequate living, are subjected to a good deal of worry. They cannot escape from officialism.

#### RESTRICTION PLACED ON BOILERS

Before the Union of South Africa was instituted the boiler inspector might go about his work in a haphazard manner. Users of steam power often were their own inspectors and if an accident occurred, resulting in the death of a Kaffir engineer, the boiler was patched up, and all went on as usual—till it again burst. Kaffir engineers were plentiful; and being fatalists, they accepted the job knowing that something unexpected might happen at any moment. Something often did, and, for that matter, trouble still arises.

The Boer farmer in the *back-veldt*, for example, has no sympathy with restrictions imposed by the British Government. Seldom does he trouble himself about having the boiler of the engine which drives his threshing-machine examined by an inspector. "It has," he argues, "lasted this season, and, if the *Allemachter* is willing, it no doubt will last another." Only when the farmer himself is hurt does he consider repairs necessary. In other respects the Boer reposes boundless trust in Providence, a belief which has gained for him the high opinion of the good missionaries, who, as elsewhere, swarm in South Africa. They even invade business premises—intent on converting the heathen.

#### APPLICANTS FOR INSPECTION JOBS

Sometimes the Boer, anxious to better himself, applies for the post of boiler inspector. But his ambition seldom is gratified, for the authorities find *Mynheer* too "slim" ("slim," in the local jargon, signifies "cunning"). He has been tried, and with the result that boilers have burst soon after Piet has passed them. The South African descendant of the old dutch settlers is ever shadowed by suspicion, and doubtless ever will be. During the South African war he gave himself away too often. The Africander (Briton born in the Union) stands a better chance, though boiler inspectors imported from England are most favored, much to the annoyance of the Africanders. Feeling runs high.

Lately the Kaffirs and Hottentots, as well as numerous halfcastes, have agitated for employment in this direction. Egged on by the missionaries, and rendered eloquent by trade gin, they have their claims, even directly with the government. The petitions have fallen on deaf ears.

The man who works in a large town has an easy enough time of it. There is no difficulty in getting about; his hours are regular; the life is one of comparative ease. When, however, he is sent to a distant railway center, the journey may be long and tiring, and the accommodation most inadequate. For the South African provincial hotel is a horror among horrors, deep in dust and dirt, and alive with fierce insects, while tinned food is a poor substitute for meat which has been freshly killed. The journey also is an expensive affair. The boiler inspector is allowed a free ticket, and, within certain limits, hotel expenses. But he must provide himself with such minor luxuries as fruit, and, in the "hot weather," ice; and if the hotel fare is found to be uneatable, a simple dainty, such as an omelette, is paid for out of his own pocket, a very stiff price being charged for it. Really, a dog's life.

#### PETTY GRAFT SOMETIMES DISCOVERED

At the same time, the Africander boiler inspector has been known to abuse the hotel allowance. One man, on returning to headquarters, produced a medical certificate to the effect that he had fallen ill—and that champagne was found necessary to his health. He put in a hotel bill which included six bottles in half that number of days. Upon an inquiry being held, it was found that the supposed invalid had been three parts drunk before retiring each night and that the doctor attending him had assisted in the consumption of the tipple. It also transpired that the boilers passed by him should have been condemned.

The delinquent lost his appointment, and it was some months before the Africander boiler inspectors recovered from the stigma thus placed upon them. The occurrence took place early last year; but it still is remembered.

#### METHODS OF TRAVEL

Sometimes the authorities at Capetown, suspecting the provincial users of steam power of employing boilers which are a menace to all who go near them, despatch a boiler inspector into the boundless *veldt*. He travels in a huge springless wagon, protected against the relentlessly fierce sun by a white tarpaulin awning, and drawn by a team of oxen, a black boy on the driver's seat. Dried *biltong*, as well as less unedible provisions, are stored in the lockers; a bed is rigged up at night; and the *Baas* carries a rifle on the chance of coming across a herd of deer. The gun also is handy in case of robbers, who, catching the occupant of the wagon unawares, may put him out of action and make way with the cattle which are dearly prized as a marketable commodity. The native, intent on turning an occasion to account, sticks at nothing.

Occasionally the oxen falling sick, die, the boiler inspector being left to reach the destined scene of activities as best he may. The unfortunate fellow has been known to perish of hunger and thirst by the roadside, his body eventually being found with the *assvogels* (vultures) and hyenas fighting over the gruesome remains. Keen though the boiler inspector is on securing the traveling allowance which is granted to all who are on *trek*, he is not always flattered by being selected for the dangerous adventure. Even a provincial hotel is preferable to being stranded in the inhospitable wilds.

The Boers, on learning of the ill-starred man's fate, show no compassion . . . "It is," they piously declare, "a judgment on the interfering one! The Allemachter has willed (Continued on page 234)

# Locomotive Boiler Failures of Recent Occurrence

The Bureau of Locomotive Inspection Reports Accidents Caused by Crown Sheet and Arch Tube Failures

SPECIAL reports recently made by the chief inspector of the Bureau of Locomotive Inspection to the Interstate Commerce Commission covering locomotive boiler accidents include several which should be given careful study by the men in the shops as well as by the operators. These reports in some detail are given below: No portion of the crown sheet showed any evidence of having been overheated, nor was the scale disturbed on the water side of the sheet other than in the pocketed area, which disturbance was caused by the bending action of the sheet as it was forced downward by the steam pressure.

The crown sheet pulled off of 57 radial stays, 41 of which

#### CROWN SHEET FAILURE CAUSES SERIOUS ACCIDENTS

The crown sheet of Chicago, Rock Island & Pacific Railroad locomotive 1935 failed while hauling a freight train at an estimated speed of 25 miles per hour, resulting in the serious injury of three employees on January 30, 1923. It left Bucklin, Kans., at 8:40 p. m., and when at a point approximately 23 miles from Bucklin, about 1 mile west of Mineola, Kans., the crown sheet failed, resulting in the injury of the engine crew who were in the cab of the locomotive at the time of the accident and who were burned by the scalding water and steam escaping from the boiler into the firebox and into the cab of the locomotive.

#### CONSTRUCTION OF BOILER

This was a 2-8-0 type locomotive with extended wagon-top boiler, equipped with radial stay firebox of three-piece construction and four arch tubes carrying the brick arch. The crown sheet was supported by 18 longitudinal and 25 transverse rows of radial stays. The six longitudinal rows of stays at the center of the crown sheet were of the button-head type with body 1 inch in diameter upset to 1 3/16 inches diameter at top and to 1 5/16 inches diameter at

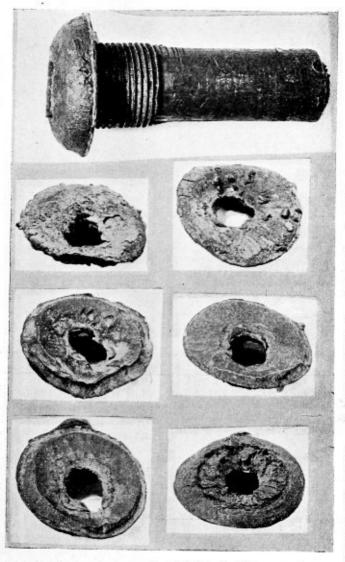

Fig. 1.-Type of Button-head Bolt Applied and Several Burned Heads Found After Accident

lower end. The remainder of the crown stays were of the driven-head type. The crown sheet was  $4\frac{3}{4}$  inches higher at the front end than at the back end.

#### EXAMINATION OF FIREBOX

The crown sheet pocketed to a maximum depth of 41/4 inches, beginning at the third transverse row of stays back of the flue sheet to and including the eleventh transverse row, and from the second longitudinal row on the left of the center line of crown sheet to the fifth longitudinal row on the right side of crown sheet, making the pocketed area approximately 48 inches long by 35 inches in width. moved and tested and found to be in good condition. The check valves had 7/16-inch lift and were in good condition. The tank, tank wells, and hose were in good condition; the right tank hose strainer was in good condition, while portions of the openings in the left strainer were obstructed by an accumulation of weeds and straw.

#### DAILY INSPECTION REPORTS

Daily inspection reports on file at Herington and Pratt, Kans., were examined and the following items which might have had a bearing on the accident had been reported and

had button heads, while the remaining 16 had hammered heads. The button heads were pulled off the stays and a number of them found in the ashes which were removed from the firebox and ash pan after the accident. The type of button-head stay originally applied is illustrated by Fig. 1, as well as the badly burned button heads that were found in the ashes. By comparing the four lower sections with the original bolt, the extent to which the button heads had been calked and distorted is apparent.

Fig. 2 (top) is another view showing the condition of a button head that still remained in the sheet after the a c c i d e n t, while Fig. 2 (lower) shows the extent to which the threads were corroded and worn away, due evidently to constant and long leakage, which is further evidenced by the condition in which the button heads were found,

#### APPURTENANCES

This locomotive was equipped with one water glass and three gage cocks, all of which were found in good condition. The lowest reading of water glass was 4 inches above the highest part of the crown sheet, while the lowest gage cock was  $5\frac{1}{4}$ inches above the highest part of crown sheet.

Injectors, safety valves, and steam gages were rewhich bear evidence of the poor condition of the firebox and flues prior to the time of the accident:

Dat 192		Defects.
Jan.	4	Calk leaks in firebox. Report approved by foreman, without notation, indicating repairs had been made.
	6	Flues leaking. Both side sheets leaking. Crown bolts leaking out of Pratt.
2		Inspect engine for other defects account of 16 hours on duty. Report approved by foreman, without notation, indicating repairs had been made.
	8	Calk all leaks in firebox. Report approved by foreman.
	12	Back end of arch-bar pipe leaking. Crown bolts and front flue sheet seam leaking. Report approved by foreman, without notation, indicating repairs had been made.
	14	Engine leaking bad, Report approved by foreman, without notation, indicating repairs had been made.
	16	Right inside arch pipe leaks in back sheet. Report approved by foreman.
	21	Calk leaks in firebox. Report approved by foreman.
	22	Flues leaking.

- Report approved by foreman. Calk all leaks in firebox. Calk stay bolts in boiler head, right side; they leak so bad when engine is working engineer can't see nor can't stand to breathe the steam. Report approved by foreman.

This locomotive was in shop at Pratt, Kans., undergoing repairs from January 24 to 30, during which time the following work was reported to have been done:

All flues expanded.

Eight to nine inches of side sheet seams rewelded.

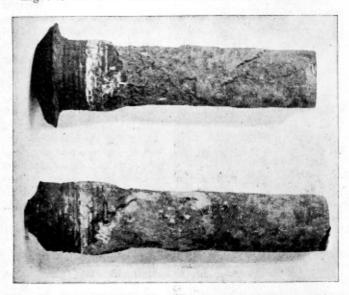

Fig. 2 .- Top View Shows Bolt Taken from Sheet After Explosion. Lower-Extent of Corrosion

Two center arch tubes applied new.

Two staybolts in right side sheet renewed.

About 50 staybolts in side sheet calked and hammered up. Boiler washed.

Left front driving wheel tire flange built up.

#### CONCLUSION

It is apparent that this failure was entirely due to the crown sheet being without proper support, due to the threads on the radial stays and in the crown sheet being badly corroded and wasted away, and the badly damaged condition of the button-head stays caused by constant calking because of leakage, until their holding power was practically destroyed.

BACK HEAD REPAIR FAILS ON PASSENGER LOCOMOTIVE

On March 10, 1923, there occurred an accident to the boiler of Richmond, Fredericksburg & Potomac locomotive 69, near Milford, Va., while hauling passenger train No.

29 at an estimated speed of 35 miles per hour, resulting in fatal injury to the engineer and the serious injury to the fireman.

The train left Washington, D. C., at 5:10 p. m., proceeded without unusual incident until near Milford, Va., about 79 miles south of Washington, when at 7:30 p.m. a crack in the right side of the boiler back head, which had been repaired by the autogenous welding process, suddenly failed, emitting steam and water from the boiler.

The force with which the scalding water and steam escaped through the rupture compelled the engineer to leave the cab without being able to close the throttle or apply the brakes in order to stop the train in the usual way.

The fireman, when interviewed, stated that he was standing in the left gangway when the accident occurred, describing the noise as a ripping sound, somewhat like the explosion of a firecracker, and said that when he turned to look into the cab after the explosion the engineer was standing on the cab deck enveloped in steam and water. He and the engineer then climbed out around the left side of the cab to the running board and to the front end of the locomotive, where the angle cock was opened, applying the brakes in emergency, which brought the train to a stop.

Our investigation disclosed that on April 13, 1921, a crack in the right side of boiler back head was repaired by the autogenous welding process. The welding had been reinforced and covered an area of 31/2 inches wide by 253/4 inches long. Soon after this another crack developed 21/4 inches to the right, 13 inches long, and parallel to the original The latter crack was also repaired by the autogcrack. enous welding process at a later date, not definitely established, but it appears from such information as we were able to obtain that this repair was made on or about April 14 or 15, 1921, soon after the first crack developed. It was the latter crack which failed, causing this accident, which indicates that the welding had been done approximately 23 months prior to failure. Fig. 3 illustrates the method of repair and the extent of the crack. When the failure occurred the crack extended three-fourths inch at the bottom and 73/4 inches at the top, making a total length of 211/2 inches.

Richmond, Fredericksburg & Potomac passenger-train locomotives are housed and repaired while in Washington at the Washington Terminal Co. shop. On February 22, 1923, while at the Washington terminal shop, there was reported on locomotive 69: "Staybolt leaking, inside of cab, left side." An examination disclosed that a crack 8 inches long on the left side of boiler back head, which had been repaired by the autogenous welding process, had opened up. Repairs were then made by applying a patch 23 inches in length and 73/4 inches wide over the crack.

This and other similar accidents which have occurred are conclusive evidence that repairs of this nature should not be permitted except where the welding is covered by a patch properly applied, which will prevent such accidents in case of failure of the welded seam.

It is impossible to estimate the serious results which might follow an accident of this nature to a fast-moving passenger train or any other train where the enginemen are forced to leave the cab without being able to close the throttle or apply the brakes, thus leaving the train to proceed uncontrolled.

#### Arch Tube on Pennsylvania Locomotive Fails

On May 5 an arch tube pulled out of the throat sheet of Pennsylvania locomotive 8255, resulting in the serious injury of the engineer and the fireman while drifting "light" at an estimated speed of 5 miles per hour; steam pressure about 180 pounds.

The engineer stated that after the failure occurred he could not see anything in the cab, because of the flames and escaping steam, and that he left the engine, ran to the rear of the tender, and opened the angle cock to apply the brakes, which brought the engine to a stop. The fireman was sitting on the seat box at the time of the accident and jumped out of the gangway to avoid the flames which struck him in the face. This locomotive was equipped with automatic fire door, which remained closed and possibly prevented more serious injuries.

#### EXAMINATION OF ARCH TUBES

This locomotive was equipped with five arch tubes  $3\frac{1}{2}$ inches in diameter. Examination disclosed that the right No. 2 arch tube had pulled out of the throat sheet and had been forced down below the hole by the weight of the brick

Fig. 3.-Fatal Crack Occurred in a Welded Repair Job

arch, thus leaving the 3½-inch hole open, through which the water and steam in the boiler escaped into the firebox and cab. The end of the tube showed that the tube had extended into the water space about one-eighth inch, but had not been belled or beaded to secure it in place and had not been sufficiently rolled to leave an impression on the tube.

Examination of the other arch tubes disclosed that they had not been properly applied. The back end of the tube which failed extended into the water space about fivesixteenths inch. The back end of the center tube extended into the water space about one-fourth inch and the front end was flush with the water side of the flue sheet. The left No. 2 tube extended through the sheet about three-sixteenths inch at the back and five-sixteenths inch at the front and showed indications of a slight leak at the back end. The right and left No. 1 tubes extended through the sheets about three-eighths inch; however, none of the arch tubes had been belled or beaded to secure them in place.

While records were not produced showing when or where these tubes were applied, information tends to show that they were applied in November, 1922, at Shire Oaks, Pa. Various inspections at the time of repairs indicated the condition of the tubes to be "good," notwithstanding it is evident that these tubes were improperly applied and that they were in an unsafe condition at the time of the inspections referred to.

The unsafe condition created by arch tubes which are not properly rolled and belled or beaded to secure them in place and kept clean and free from scale while in service is so generally well recognized that comment hardly seems necessary, as the requirements are so clearly set out and described by the law and rules.

#### ANOTHER ARCH TUBE FAILURE

At 1:50 p.m. on June 7, 1923, an arch tube pulled out of the throat sheet in boiler of Pennsylvania railroad locomotive 8854, resulting in the serious injury of one employe.

Locomotive 8854 was equipped with four arch tubes 3 inches in diameter. The investigation disclosed that the tube which pulled out of the sheet had not been applied at right angles with the sheet, it being flush with the water side of the throat sheet at the top and extended into the water space only  $\frac{1}{8}$  inch at the bottom and was not belled or beaded at either end to secure it in place. The other arch tubes were badly mud burned and blistered, right No. 1 tube had four blisters, left Nos. 1 and 2 tubes had six and ten blisters, respectively.

#### CONDITION OF FIREBOX

The flues had been electrically welded to the back flue sheet, many of which were cracked and in bad condition. A patch had been applied to the knuckle of the back flue sheet and was found in bad condition, and had been since May 1.

It could not be ascertained when or where the arch tubes were applied. The monthly locomotive inspection and repair report dated at Logansport, Ind., on May 18, 1923, subscribed and sworn to by the inspector and approved by the officer in charge, shows the flues, firebox sheets and arch tubes to be in "good" condition, which could not be correct as disclosed by the official investigation of this accident and as evidenced by the frequent reports showing the defective condition of the firebox prior to the date of the sworn report.

## An Exact Method for Developing a Cone By Wilson Blackburn

IN an endeavor to help the readers of the BOILERMAKER, I submit the following enclosed sketches and calculations together with an example of the only true way of laying out a cone, other than by use of trammels. Too often in the past the average writer when solving for the versed sine has lost sight of the fact that the stretchout of a cone is in reality an arc of a circle. The solution I present is equally correct for a cone made up of numerous sections as a cone of one piece providing the layout divides the angle A of the stretchout and the length of the arc by the number of pieces, when getting out a section of the chord E. No doubt this will be criticized on account of the use of trigonometry, but it is up to every layerout to study and master the intricacies of "trig" as the day is not far distant when approximate methods will no longer be tolerated.

To find the radius of the cone we must find the angle a  $\frac{1}{2}(D-d)$ 

of the sketch as follows: tangent angle  $a = \frac{\frac{1}{2}(D-d)}{C}$ ,

radius 
$$R = \frac{\frac{1}{2} (D - d)}{\text{Sine } a}$$
. Next to find the length of the

chord E which is the first line necessary to begin the development, we must first calculate the number of degrees enclosed within the arc or stretchout as follows: angle

$$=\frac{57.29578\times D}{R}$$

A

#### THE BOILER MAKER

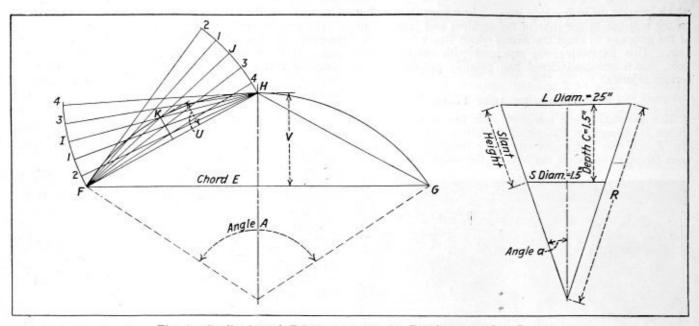

Fig. 1.-Application of Trigonometry to the Development of a Cone

The chord E is then  $2(R \times \text{sine } \frac{1}{2} \text{ angle } A)$ .

The versed sine  $V = (1 - \cos \frac{1}{2} \operatorname{angle} A) R$ . We now have three points required for the development. Lay off the length of chord E as per example and on its center erect a perpendicular equal in length to the versed sine V. Mark these points respectively F, H and G. Connect H to G by a straight line, also H to F. Now to determine another point on either side of H we find the versed sine Uas follows:  $U = (1 - \cos \frac{1}{2} \text{ angle } A) R$ . Half way between points H and F erect a perpendicular equal in length to this versed sine U. Now from H and F respectively with a radius equal to H-F, strike arcs as shown in example. Next draw lines from H through the point K and from Fthrough K, each line cutting one of the arcs locating points I and J. Lay off equal spaces on either side of I and Jnumbering them as per example. Lines drawn from H to these spaces so found will cut lines of the same number drawn from F to the other arc, locating some more points which when struck through by a curve gives the true camber line.

To lay out the other circle the trammels may be used set to the length of the slant height which may be found by

C"trig." slant height = -Cos angle a EXAMPLE Tangent angle  $\alpha = \frac{\frac{1}{2}(D-d)}{2}$  $=\frac{\frac{1}{2}\times 1}{=}=\frac{.5}{.5}$ 1.5 =.3333 $= 18^{\circ} 26' \frac{1}{2} D$ Angle a  $\frac{\frac{1}{2}D}{2} = \frac{\frac{1}{2} \times \frac{2}{2}}{2} = 3.96''$ Radius R =.31620 Sine a  $57.29578 \times 3.1416 \times 2.5$ Angle A = -3.96  $= 113.8^{\circ}$  $\frac{1}{2}$  Chord  $E = R \times \text{Sine } \frac{1}{2}$  angle A  $= 3.96 \times \text{Sine } 56^{\circ} 54'$ = 3.96  $\times$  .83772 = 3 5/16''

Chord E	= 6 5%"
	$= (1 - \cos \frac{1}{2} \text{ angle } A) \times R$
	$=(154610) \times 3.96$
	$=.4539 \times 3.96$
	=1.797 = 1 25/32''
Versed Sine $U$	$=$ (1 - Cos $\frac{1}{4}$ angle A) R
	$= (1 - \cos 28^{\circ} 27') \times 3.9$
	$= (187923) \times 3.9$
	$= .12077 \times 3.9$
	= .47 in. $= 13/32$ in.
Vancouver, B. C.	WILSON BLACKBURN.

#### Boiler Inspecting in South Africa

#### (Continued from page 230)

that his bones should bleach in the sun!" . . . Delightful people—to avoid.

When the boiler inspector is on *trek* he may turn the occasion to account by superintending the patching-up of a much worn engine, for a knowledge of mechanical engineering often is his. The fee paid is a trifling one; but, as the native dictum so aptly puts it, "the pile of silver eventually is turned to gold." So, with luck, the expert returns from the official trip richer than when he started. He also has a chance of filling the wagon with country produce; bales of ostrich feathers and other saleable lines.

The government objects to the boiler inspector putting official time and the official vehicle to unofficial use; and, when instances are discovered, it may go ill with the offender. The astute speculator who is sufficiently wide-awake (and he usually is very "slim") outspans at a convenient point, transferring the merchandise to another wagon and pursuing a blameless way to headquarters. Having reported to his superior and handed in the necessary papers, he is at liberty to turn to commercial negotiations. The "slim" boiler inspector generally does well out of such dealings. Some years ago the inspector's *trek* brought him into contact with natives who had acquired diamonds under suspicious circumstances, and he who was not particular would do a deal without asking convenient questions of the seller.

When the boiler inspector has to examine a Boer-owned boiler, the copy of the report which is given to the owner of the plant is in *Taal*, the mother-tongue of these people. Many of them are by way of speaking English, with a strange colonial accent; but the "*Taal*" is their recognized language. 'Tis considered unpatriotic to know any other.

From time to time, articles dealing with methods of high power boiler inspection have been published in THE BOILER MAKER, but since these have represented the practice of individual companies there has been an opportunity for differences of opinion as to the best procedure. The rules for power boiler inspection published elsewhere in this issue should prove to be of great assistance to those who build boilers as well as to those who operate and inspect them since they indicate the specific safety requirements to which A.S. M.E. boilers will be held.

These rules constitute a section of the preliminary report of a sub-committee of the A.S.M.E. Boiler Code Committee prepared on the operation and care of power boilers. The rules apply to steam boilers constructed in accordance with Part I Section I of the Boiler Code and to those not subject to Federal inspection and control including marine boilers, boiler of steam locomotives and other types. Every shop in which the men make a study of their work has a veriety of time and labor-saving appliances built from materials at hand without a very great expenditure of time or money. In every case such equipment promotes the efficiency of the shop in a small way and makes one or more of the operations to which it can be adapted easier to perform.

A number of the devices that have been built and used successfully and that can be made and applied wherever men are interested enough to put them together, are shown in another part of this issue. Further articles describing timesaving devices and shop kinks will appear later.

Practically every one of our readers will admit that material of this kind is helpful but, since a single contributor cannot cover all the shops in the country and dig out the thousand-and-one time savers that every shop has developed, we want more of our readers to join the ranks of those who write for THE BOILER MAKER. It is not practicable to write individually to our subscribers, asking them about their work, but this request is to be considered a personal invitation to every one to communicate more frequently with us and tell the rest of the trade what he is doing through the medium of our pages.

Real progress is being made in the art of autogenous welding—the measure of this advance being indicated by its successful applications. In the boiler making industry and allied fields, welding is playing an increasingly important part. In high pressure boilers it can be applied to advantage where the welds are not required to carry the stress, as an aid to tightness and strength.

In Scotch marine boiler construction, certain shops make a practice of welding seams and stay nuts in the combustion chambers to a point 2 feet above the center line of the furnace. Inside and outside butt strap edges are welded. Saddle lug calking strips are welded to the boiler shell. Combustion chamber seams exposed to the direct action of the flame are welded inside and out to protect the plate edges against possible leaks. Screw stays up to 2 feet above the center line of the furnace are fitted with special round collar nuts which are welded after being screwed on the stays.

Low pressure all-welded steel boilers are being built in competition with other types of heating boilers at a greatly reduced production cost. The boilers so constructed have proved extremely serviceable and uniform in their operating characteristics.

High pressure tanks, chemical retorts, pressure cooking pots, as well as storage tanks for a variety of purposes are being welded on a production basis at various shops throughout the country with great success.

When the recommendations of the Pressure Vessel Committee of the American Bureau of Welding resulting from the tests conducted at the Bureau of Standards in Washington from December 4, 1922, to February 1, 1923, have been considered by the A.S.M.E. Boiler Code Committee with a view to the final formulation of the pressure vessel code, a more widespread and more uniform application of welding will be possible in this industry. The recommendations of the Pressure Vessel Committee will be published in full in a later issue of this magazine.

# Engineering Specialties for Boiler Making

New Tools, Machinery, Appliances and Supplies for the Boiler Shop and Improved Fittings for Boilers

## Semi-Hot Bolt Header with Automatic Feed

A NEW and radical design of one-inch, semi-hot bolt and rivet header with automatic feed has been developed by the engineers of the National Machinery Company, Tiffin, Ohio, and recently placed on the market. The bed frame in the new design, illustrated in Fig. 1, is

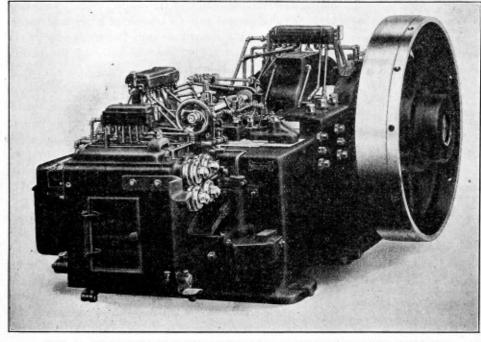

Fig. 1-National Semi-Hot Bolt and Rivet Header with Automatic Feed

only half as long as in previous models, and spring is practically eliminated, making it unnecessary to batter the heading tool against the gripping dies to properly fill out the head of the work. Some idea of the great strength and stiffness of the design is indicated by the fact that while the machine weighs 31,500 pounds, it is only 513/4 inches from the center of the main shaft to the face plate, and the main shaft at the crank is  $11\frac{1}{2}$  inches in diameter.

The hard service and consequent wear on earlier automatic feed headers has been met by greatly increasing the size of all bearings and working surfaces, and adopting such features as the "suspended type" heading and gripping slides with bearings above the path of scale and water. All of the gripping toggles have been increased in size and are located horizontally to insure proper lubrication. The ultimate pressure that can be thrown upon the toggles and gripping mechanism is limited by a new type of automatic relief, making destructive pressures impossible. Last but not least, a fully automatic oiling system which oils every bearing of the machine automatically every ten minutes is provided, supplying a predetermined amount of oil for each bearing, proportionate to its service requirements. In a three-year test period, several machines of the new type have required no repairs or relinement, and working parts show practically no appreciable wear.

The previous trouble in die setting, resulting from the lack of a horizontal adjustment for the heading tool, has been overcome by mounting the heading tool in a bolster plate on the front of the heading slide, which, being screwcontrolled in all directions, provides for quick and accurate adjustment of the heading tool with the gripping dies. This construction is outlined in Fig. 2.

> The lack of control of the gripping or holding time in the old machines has been corrected by providing an adjustment in the gripping toggles. Consequently, on work requiring minimum gather or hold, such as rivets, it is possible to reduce the holding time to the exact requirement. On work such as 1-in. U. S. square head bolts, or any work requiring a large amount of gather, the gather is obtainable by means of this adjust-The practical result of ment. limiting the contact with the heated stock is a reduction in heating effect on the dies and lengthening of die life.

> One of the difficulties of the old type of machine was an inherent defect in the design of the shearing mechanism, which tended to badly distort the end of the sheared bar, making it difficult to center the next head. This condition has been corrected in the new design by building the feed mechanism at an angle to the machine proper. This

gives an angling shear, which, by compensating for the distortion, results in central heads, and makes it possible to upset and fill out an increased length of stock for large heads.

The powerful shearing and gripping mechanism, combined with the great strength and stiffness of the machine, enables work to be made at unusually low temperatures.

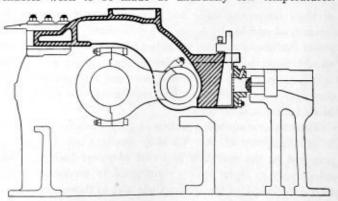

Fig. 2—Diagram Showing Heading Slide and Bolster Plate Construction

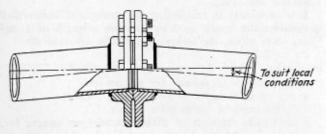

Rivets are made at 1,000 to 1,100 degrees F., and bolts at 1,200 to 1,500 degrees F. Records in big bolt plants show that the life of heading tools has been doubled and of gripping dies tripled.

## Life of Boiler Washing Plants Increased

THE rapid deterioration of enginehouse piping has been the cause of excessive maintenance costs for boiler washing plants. By the development of a so-called leadizing process of coating roundhouse piping, after the pipe is fabricated ready for installation, with a lead surface of sufficient thickness to withstand the abrasion due to ordinary handling and by substituting drop forged flanges shrunk and welded on the pipes, for threaded connections, the National Boiler Washing Company, Chicago, has overcome much of this excessive cost of maintenance.

The greatly increased permanency of the enginehouse piping thus provided makes practicable an initial installation of hot water boiler washing and filling equipment with mains of sufficient size to permit the future installation of additional capacity at comparatively small expense. The development of the tandem condenser permits the installation of additional condenser units as they may be needed to increase the number of locomotives that can be handled at one time, the additional storage capacity being provided by increasing the number of tanks up to the capacity of the mains.

Prior to the development of the leadizing process the greatest difficulty from corrosion was found to develop at the threaded connections. In order to eliminate this weak point and to overcome the additional weakness caused by bending the pipes to conform to the circle of the enginehouse the drop forged flange connections shown in the drawing were developed to replace the threaded connections. With these connections the roundhouse mains are laid out in the form of chords of the circle of the house and the flanges bored out at an angle varying from the axis by an amount sufficient to bring the faces of the adjoining flanges together, with the adjoining sections of pipe located normal to the center lines of the stalls. The flanges, thus bored, are shrunk and welded to the pipe, which has been cut to length, and the faces of the flanges are then accurately ground to the correct angle in a machine especially developed for the purpose. Since the development of the leadizing process on a commercial basis

Special Welded Drop-Forged Flange

the sections of pipe thus fabricated are further protected by the addition of a strong lead coating.

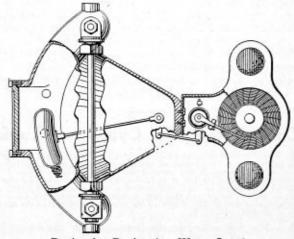

The leadizing process was first developed on the Atchison, Topeka & Santa Fe about seven years ago. It consisted in immersing the pipes or other steel to be coated in a hot bath of acetate of lead. The resulting chemical action causes the transfer of lead to the surface and iron to the bath, the action continuing only so long as any of the steel surface is exposed. The lead coating is therefore extremely thin and easily subjected to damage in handling.

To provide a commercially practicable coating the National Boiler Washing Company completes the lead 'deposit by a heavy electro plating process. After this the material is thoroughly washed and painted.

### Water Recorder Promotes Safety

RECORDING device which maintains a 24-hour graphic record of the water level in a boiler has been developed by the Hackman Manufacturing Company, Milwaukee, Wis., under the name of the Hackman water recorder. Besides the continuous water level record, the device indicates the time the boiler was cut in, or cut out; how long the water was too low or too high; whether or not the water was foaming; whether the water glass has become clogged and other facts which should be known by the operator to realize the proper efficiency from the boiler.

The recorder consists of a water column constructed of steel connected to the water supply and to the boiler. In this

Device for Registering Water Level

column is a copper covered cork float connected with a suitable lever mechanism to the registering device. A waterproof union with the registering device at the right of the triangularshaped float arm box prevents interference with the registering mechanism. A spring on the bottom of the float prevents the closing of the intake in the event that water gets too low in the boiler. The float is also connected to a gong, so that if the water level falls or rises above a determined level which the float mechanism is set to record, an alarm is sounded which continues until the water level has been restored. Two light signals are also operated by the float. The recorder is simply installed in place of the usual water column.

### BUSINESS NOTES

D. W. Phillips, formerly connected with the Heine Boiler Co., in the capacity of shop superintendent of their St. Louis Mo., plant, is now shop superintendent with the International Engineering Works, Framingham, Mass.

C. C. Rosser, who for many years has been connected with the Detroit Seamless Steel Tubes Company, Detroit, Mich., has been appointed district sales manager with offices at 1206 Guardian building, Cleveland, Ohio.

The Surplus Steel Exchange, Inc., 7 Dey Street, New York, which was recently organized, announces the opening of an office in Chicago, at 2257 Oakdale Avenue, in charge of A. E. Thiffault and Raymond I. Caspers.

The Connecticut Blower Corporation, Hartford, Conn., has been incorporated under the laws of Delaware with capital of \$250,000. M. E. Keeney, President, C. H. Keeney, Treasurer, C. E. Keeney, Secretary. This company has taken over the International Blower Company and the Hartford Sheet Metal Works.

# Questions and Answers for Boiler Makers

Information for Those Who Design, Construct, Erect, . Inspect and Repair Boilers—Practical Boiler Shop Problems

Conducted by C. B. Lindstrom

This department is open to subscribers of THE BOILER MAKER for the purpose of helping those who desire assistance on practical boiler shop problems. All questions should be definitely stated and clearly written in ink, or typewritten, on one side of the paper, and sketches furnished if necessary. Inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

## Conical Roofs for Cylindrical Tanks

Q.—Please publish in proper order in "Answers" Dept., your own, or any other logical system, or method, of arriving at the following required data: Given:—The diameter of any vertical storage tank (for example, 10 feet 0 inch diameter and 30 feet 0 inch diameter). Required:—The minimum height of self-supporting roof, and minimum thickness of steel plate. This result as regards height and thickness of plate of course being for average snow and wind loads. The sketch on the attached sheet makes the above as plain as possible.—H. B. F.

A.—The following specifications on tank roofs have been adapted by the American Bridge Company:

The top of the tank will generally be covered with a conical roof of thin plates; and the pitch shall be 1 to 6. For tanks up to 22 feet in diameter the roof plates will be assumed to be self-supporting. If the diameter of the tank exceeds 22 feet, angle rafters shall be used to support the roof plates, which are generally  $\frac{1}{8}$  inch thick.

Plates of the following thickness will be assumed to be self-supporting up to 22 feet in diameter:

3/32-inch plate, up to a diameter of 18 feet.

1/8-inch plate, up to a diameter of 20 feet.

3/16-inch plate, up to a diameter of 22 feet.

Rivets in the roof plates are from  $\frac{1}{4}$  to  $\frac{5}{16}$ -inch in diameter, and are driven cold. These rivets need not be headed with a button set.

Where angle rafters are employed the load due to wind and snow is assumed to be 30 pounds per square foot. The load therefore is figured for a segment of the conical roof which may be assumed as triangular in shape.

For all practical purposes the size of the angle rafters is determined by considering the rafter a beam uniformly loaded, supporting the load due to the weight of the conical segment and the load due to wind and snow.

The bending moment of such a beam is determined from the formula:

$$M = \frac{W \times L}{8}$$

in which, M = bending moment pounds.

W = the load in pounds on the beam.

L = length of beam in inches.

is the safe stress in pounds per square inch on the structural seam.

From a structural handbook the size of the angle is indicated for the calculated section modulus.

## Bursting and Working Pressure, Factor of Safety, Types of Blow-Off Valves and Connections

Q.—(1) If the factor of safety on a boiler were 5 and the boiler pressure 200 pounds per square inch would the bursting pressure be  $200 \times 5 = 1,000$  pounds? (2) A vertical firetube boiler recently came to my attention which did

pounds? (2) A vertical firetube boiler recently came to my attention which did not have a globe valve in the steam space which would act as a blow-off valve. Does not the A. S. M. E. Boiler Code require that there should be one at this place and that the valve above the waterleg of the boiler must be at least one inch and not greater than 2% inches (pipe size U. S. standard)? This boiler had a globe valve instead of a straightway valve for the mudring blow-out. Is this permissible?—C. B.

A.—The force tending to rupture a cylindrical boiler shell longitudinally, as on the plane *a-b-c-d*, Fig. 1, is repre-

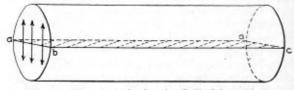

Fig. 1.-Pressure Acting in Cylindrical Shell

sented by the inside diameter multiplied by the pressure times the shell length. Thus consider the inside diameter *a-b* of the shell to equal 60 inches, length of shell 12 feet or 144 inches and the steam pressure 100 pounds per square inch. The total pressure acting in the direction of the arrows is equal to  $60 \times 144 \times 100 = 864,000$  pounds.

The strength of the shell to resist the pressure equals the resistance or tensile strength of the metal taken along the sides b-c and a-d.

It is customary in calculating the strength of boiler shells to consider the length as unity, that is, a length of 1 inch. Using data given, the following formulæ are evident:

Pd = 2tS

in which:

P = pressure in pounds per square inch.

d = inside diameter of boiler shell, inches.

t = thickness of boiler plate, inches.

S = tensile strength of plate, pounds per square inch. Pd

and (2) 
$$t = -\frac{2S}{2S}$$

As boiler shells are formed with longitudinal seams and as the joint is weaker than the solid plate, the strength of the joint as compared with the solid plate, known as the joint efficiency, must be taken into account. In addition to this, it is necessary to employ in the calculations a factor of safety. The factor of safety may be explained as the ratiobetween the safe working pressure and bursting pressure. For new boilers a factor of 5 is specified by the A. S. M. E. Boiler Code.

Representing the factor of safety by F and the efficiency-

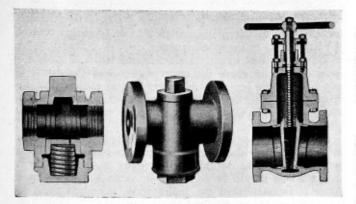

Fig. 2 (a).—Two Views of Blow-off Cock Fig. 2 (b).—Gate Valve (At Right)

of the longitudinal joint by E and using their values in connection with those of formula (2), the following formula (4) is produced.

(4) 
$$t = \frac{PdF}{2SE}$$
  
rom which;  
(5)  $P = \frac{2tSE}{2}$ 

f

(5) 
$$P = \frac{1}{dF}$$

Example: Assuming that a boiler 60 inches inside diameter is to be built to carry 100 pounds per square inch from steel plate having a tensile strength of 55,000 pounds per square inch, efficiency of longitudinal joint to equal 80 percent; factor of safety, 5; determine the required plate thickness. Solution:

Using these values in the formula (4)  

$$t = \frac{100 \times 60 \times 5}{2 \times 55,000 \times 0.80} = 0.341 \text{ inch}$$
Using the plate thickness in the formula (5)  

$$P = \frac{0.341 \times 2 \times 55,000 \times 0.80}{60 \times 5} = 100 \text{ pounds}$$

per square inch.

If the allowable working pressure on a boiler is 200

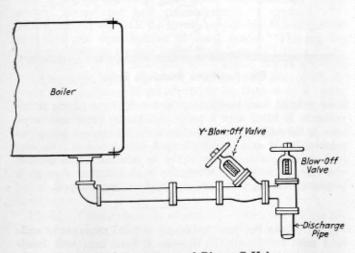

Fig. 3.-Arrangement of Blow-off Valves

pounds per square inch and the factor of safety 5, the bursting pressure equals  $200 \times 5 = 1,000$  pounds.

For blow-off connections there are three types of valves commonly employed. In Fig. 2 (a) is represented a blowoff cock, and in (b) a gate valve. The blow-off or plug cock is used for surface blow-offs, especially on low and medium steam pressures. The tapering plug a, as will be noted, is held in place by a compensating spring b which automatically takes up wear.

#### VALVES FOR HIGH PRESSURE

The valve shown is of the extra heavy pattern used for high steam pressures. Blow-off valves are subjected to severe service due to the dirt and scale that is present at the bottom of the boiler. These substances in passing through the valves tend to cut the valves and valve seats; for that reason the valves should be opened wide for the blowing off operation. The section view (b) shows the interior construction of the valves and their body.

In Fig. 3 is shown a bottom blow-off connection with a Y pattern blow-off near the boiler and blow-off valve that connects with the discharge piping and Y blow-off. Every boiler blow-off should be equipped with two blow-off valves or a blow-off cock and a blow-off valve.

To blow down a boiler the Y or blow-off cock should be opened first and the blowing off controlled by the blow-off valve. When completing the operation the blow-off valve is closed first, then the Y or blow-off cock. Globe valves should not be used for blow-off valves.

The following rules on blow-off piping and valves are quoted from the A. S. M. E. Code:

Par. 307. Blow-off Piping. A surface blow-off shall not exceed 1¹/₂-inch-pipe size and the internal and external pipes, when used, shall form a continuous passage, but with clearance between their ends and arranged so that the removal of either will not disturb the other. A properly designed brass or steel bushing or flanged connection, shall be used.

Par. 308. Each boiler shall have a bottom blow-off pipe, fitted with a valve or cock, in direct connection with the lowest water space practicable; the minimum size of pipe and fittings shall be 1 inch and the maximum size shall be  $2\frac{1}{2}$  inches. Globe valves shall not be used on such connections.

Par. 309. A bottom blow-off cock shall have the plug held in place by a guard or gland. The end of the plug shall be distinctly marked in line with the passage.

Par. 310. The blow-off pipe or pipes shall be extra heavy from boiler to valve or valves, and shall run full size without reducers or bushings. All fittings between the boiler and valves shall be of steel.

#### EXTRA HEAVY VALVES

Par. 311. a On all boilers except those used for traction and portable purposes, when the maximum allowable working pressure exceeds 125 pounds per square inch, each bottom blow-off pipe shall have two valves, or a valve and a cock, and such valves, or valve and cock, shall be extra heavy, except that on a boiler having multiple blow-off pipes, a single master valve may be placed on the common blow-off pipe from the boiler, in which case only one valve on each individual blow-off is required.

b Every traction and portable boiler shall have a bottom blow-off valve; when the maximum allowable working pressure exceeds 125 pounds per square inch, the blow-off valve shall be extra heavy.

Par. 312. A bottom blow-off pipe when exposed to direct furnace heat shall be protected by firebrick, a substantial cast-iron removable sleeve or a covering of non-conducting material.

Par. 313. An opening in the boiler setting for a blow-off pipe shall be arranged to provide for free expansion and contraction.

## Water Level in Watertube Boilers

Q.—Please send me the official data on the amount of water to carry in watertube boilers. 'I want this information to tack on the blackboard. We had a low pressure 5-pound steam and vacuum system to our radiators; a high pressure 60-pound to our hot water boilers and drips. It was changed a few years ago to get the knock out of the system, and all hooked into the low returns. It is worse than before the change. High pressure traps blowing, stops circulation in the low and make more noise than ever. Would you advise changing back again?—J. A. K.

A.—The required water level in watertube boilers depends on the type of such boilers. For the Babcock and Wilcox type, Fig. 1, the waterline is at the center of the drum a, as

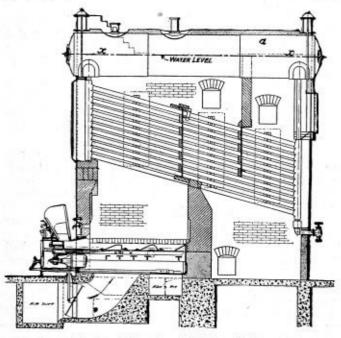

Fig. 1.-Babcock and Wilcox Boiler

indicated along the line x-x. Boilers of similar type in which the steam and water drums are horizontal the water level is at the center along the drum axis.

For the Sterling watertube boiler, Fig. 2, the water level is indicated in the three drums, a, b and c. As the drum b is higher than the drums a and c, the water level is lower in the

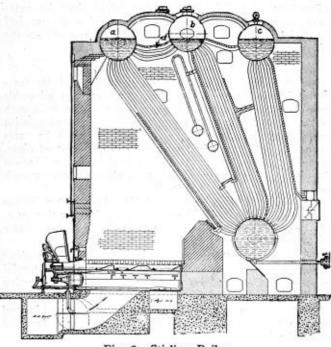

Fig. 2.-Stirling Boiler

drum b. The water line in the drum b should be at least 2 inches above the circulating tubes d; this condition controls the water level in the other drums.

The water level in the standard Heine boiler, Fig. 3, is 2 inches vertically above the center line a-a of the drum, as measured at the center of the drum and as indicated in the illustration. This brings the water level at the center of the water gage b. In the cross drum type the waterline is at the center of the drum.

Most boilers are so designed that the proper water level is obtained when the water glass gage is half full. There may, be exceptions to this, but in any case the maker's specifications should be followed, to locate the water level. After it is established the boiler room attendant must be instructed as to the required water level.

In running the high pressure steam to the returns of the low pressure side the system is reversed and naturally will not work properly. In such a case the circulation would tend to equalize and the steam would blow through the traps and water hammer may result. The radiators would also be affected by the higher pressure.

As we have not complete data on the piping it is difficult to

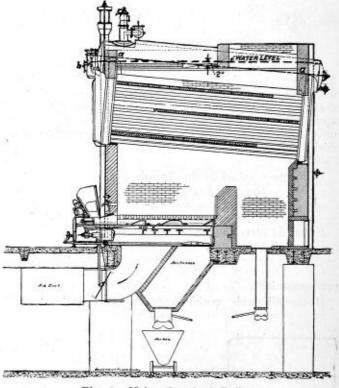

Fig. 3.-Heine Standard Boiler

make definite recommendations, however, if the piping to the radiators is fitted with a pressure-reducing valve and traps used in the return, in conjunction with the vacuum pump, no trouble should arise in that branch of the system. On the high pressure side, if the steam is returned from the hot water heater into the low returns it should pass through a pressure reducing valve and the condensation trapped.

J. P. Moses has been appointed general manager of railroad sales for Joseph T. Ryerson & Son, Inc., with headquarters in the Illinois Merchants Bank Building at Chicago. H. T. Bradley has been appointed manager of eastern railroad sales with headquarters at 30 Church St., New York. H. A. Gray, formerly manager of railroad sales, resigned to enter another field of business.

## Letters from Practical Boiler Makers

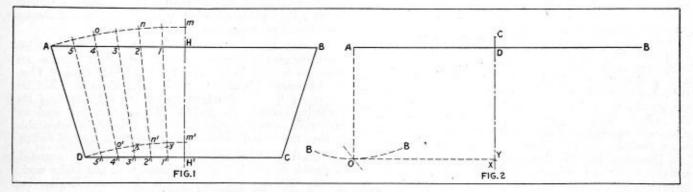

This Department Is Open to All Readers of the Magazine -All Letters Published Are Paid for at Regular Rates

## Wrapper Sheet Camber Layout

HAVE seen many different methods used for obtaining the camber of a ladle wrapper or tank, stack or other conical course where the conical height is too great to permit layout with a sweep and it is wished to avoid triangulation. Some of them are theoretically exact but involve awkward constructions which make them impractical while the "snap" methods are not to be relied on for heavy

From C as a center with A-X as a radius strike an arc intersecting B-B as at O.

The points A and O thus determine a true radial line A-O and after drawing O-Y perpendicular to the centerline C-X we may proceed with the half figure A-D-Y-O in the same manner as with Fig. 1. In this case the point Cmay be used to check the exactness of the work since it should correspond with the last point found as m in Fig. 1. If carefully followed, the procedure of Fig. 1 will always

Method of Obtaining Camber of a Ladle Wrapper, Tank or Stack

plate work where accuracy is desirable. I myself have a partiality for accuracy in laying out work and I believe the method I submit herewith is superior to any other since it is both simple and absolutely exact. Once understood, it is easily used and always insures a true shape as may be easily proved by working up a short beveled cone as shown and checking the curve with the trams.

Construct A-B-C-D, Fig 1, making A-B and D-C equal respectively to the large and small circumferences of the conical course (or half circumferences if desired). Illustrating only one-half the stretch-out, divide A-H and D-H' into the same even number of equal spaces. Through the corresponding points thus found draw lines as 1-1', n-2', etc. Set the trams to A-5' and using this distance as a radius from 5' as a center locate the point o on the line o-4'; similarly from o as a center locate the point x; from x as a center locate n; from n as a center locate y; and from y as a center locate m.

Set the trams to the slant height of the course-in this case A-D is used-and from the points o, n, and m locate respectively o', n', and m'. Through points A, o, n and m, draw a curve for the large circumference and in the same way points D, o', n' and m' determine the curve of the small circumference.

Finally if the camber is considerable, measure off on the curves thus found the exact circumferential lengths desired which completes the lay-out. The same method may with slightly different procedure be used to construct a true arc of a circle of any diameter having known as in Fig. 2 the chord A-B and rise C-D.

Extend C-D to any convenient length as C-X and from A as a center using C-X as a radius strike an arc as B-B. insure fair holes regardless of the difference between the large and small diameters and is much quicker than development by triangulation. Houston, Texas

R. L. PHELPS

## A Plea for Better Supervision of Boilers

ONDITIONS as outlined to us by Mr. C. W. Carter in the July issue of THE BOILER MAKER (page 214)

regarding locomotive boiler inspection are not very reassuring to those entrusted with the operation of engines or to the public at large. We have heard of such conditions and, as Mr. Carter in various issues of THE BOILER MAKER has given us articles that were both interesting and instructive. some attention should be given to his remarks. The condition exists, what is the remedy?

It is true, the shop boiler inspector does not have to pass an examination, but he should be compelled to do so, an examination along the same lines as the state codes require from their inspectors. Then he should have had not less than five years' experience as a boiler maker apart from his apprentice service. Having these necessary qualifications, there is only one more thing necessary, apart from good judgment, and that is, back-bone.

Our Federal laws put it squarely up to the inspector, not to his foremen or his master mechanic and, if he reports defects that are dangerous, or come within the meaning of the law as so written, he can refuse to sign the forms and that is where the back-bone is required.

Mr. Carter does not state what railroad he is working for, but at the local shops of the Baltimore and Ohio Railroad where I am employed such conditions do not exist, traffic is heavy, the lake coal season is in full swing, but every one of us in the boiler department takes pride in the knowledge that the boilers that come under our care are as safe as the day they were built.

We have a competent boiler inspector and, when he reports defects that tend to weaken the boiler, repairs must be made before he will sign the forms and, in all fairness to his superior officers, there is never any trouble on that account. I suggest as a remedy for such conditions as outlined by Mr. Carter:

1st. Competent inspectors-with back-bone.

2nd. Supervising officials, with common sense and the willingness to cooperate with their boiler inspector.

Lorain, O.

JOSEPH SMITH.

## In a Pinch

TOW many times through carelessness have staybolts marked on one end to be renewed been marked wrong on the opposite end?

Just such a condition occurred on an old-type locomotive boiler, which required much more consideration than merely renewing an extra staybolt to remedy the mistake. The boiler in question had the lower half set of flues renewed, defective staybolts removed and some minor firebox repairs done while in shop. When the hydrostatic test was applied to see that all the work was tight, the inspector found a staybolt leaking through the tell-tale hole. It was located on the center of the throat sheet, top bolt, and was marked outside to be renewed but never marked on the opposite end in the firebox. The foreman after receiving the report sent a three-year apprentice, helper and an acetylene burner to renew the bolt. This bolt was burned outside where marked, but, instead of the defective staybolt being marked, an eye bolt of a throat brace was marked and burned out on the firebox side which was located directly above the defective staybolt that was burned outside on the throat sheet.

After all the scheduled shop work was done, and the engine about ready to be put into service, it seemed out of the question to remove the dome cap, throttle chamber and standpipe and five or six rows of flues down through the center of the boiler to replace the eye bolt that was burned out in the firebox by mistake.

As the boiler would be due for a complete removal of flues in between one and two years, and a possible renewal of the back flue sheet, it was decided to burn a 5-inch diameter piece out of the back flue sheet where the eye bolt was centered. The pin, nut and cotter were then burned out, and the eye bolt removed through the 5-inch opening made in the back flue sheet.

A new eye bolt and pin with just a cotter pin hole in it was then made. Before applying same, the opening in the back flue sheet was chipped to a 45-degree angle. After this was done and the eye bolt applied, a piece of firebox steel 1/2-inch by 5-inch diameter was cut and the edge turned to a 45-degree angle (allowing enough opening for electric welding) and a 13/16-inch hole drilled in the center for the eye bolt, which was tapped out 1 inch with a 12-thread tap to fit the eye bolt thread. The plate was then screwed into place with a chisel or pointed tool and hand hammer. A steel clamp 3/4 inch by 2 inches by 8 inches with a 11/8inch hole drilled in the center and a special 12-thread nut was made and temporarily applied to hold the tension of the brace, eye bolt and plate in place while the plate was tackwelded in several places. The nut and clamp were then removed, the plate homogeneously welded, the eye bolt urned off leaving enough for the head which was then driven with a light pneumatic hammer and bobbing tool.

The fractured or original staybolt with right and left adjacent bolts were renewed and the boiler hydro tested O. K. T. P. TULIN. Jersey City, N. J.

## TRADE PUBLICATIONS

ELECTRIC STEEL CASTINGS .- A group of bulletins outlining the process of manufacturing electric steel castings and their application in industry has been collected in binder form for distribution by the Nugent Steel Castings Company, Chicago, Ill., formerly the Electric Steel Company.

BOILER TUBES .- An announcement of the New York boiler tube supply service of B. F. Keating Company, New York city, has recently gone out to the trade. Complete stock of steel, lap welded and seamless charcoal iron tubes, as well as fittings, valves, cocks and plumbing supplies are maintained in the New York district. The card also includes a number of reference tables giving tube data.

MODERN FURNACE BUILDING .- The Jointless Fire Brick Company, 9899 Clay Street, Chicago, is offering to engineers and power plant operators a booklet which tells the complete story of the building of monolithic furnace linings. It shows how boiler furnaces, circular furnaces, pit type brass furnaces and other furnaces may be lined with this jointless furnace lining. Illustrations showing how forms for special shapes, like front door arches are made, are frequent.

CONTROL RELAYS .- Control Relays, to be interposed between the circuit breaker solenoid and control switches are described in bulletin No. 47672 issued by the General Electric Company, Schenectady, N. Y. The relays described are known as the instantaneous control, type PB-53 and the hesitating control, type PB-54. These relays are used for the remote control of circuit breakers when it is undesirable to have the control current pass through the control switch.

HYDRAULIC RIVETERS .- Riveters, hydraulically actuated, applicable to all kinds of ship, plate, tank and boiler work, are described in a bulletin issued by the Hanna Engineering Works, Chicago, Ill. Illustrations and descriptions for riveters, both regular and special type, are given in sizes from the 6-inch reach, 8-inch gap, 15-ton capacity, forged nose riveter to the 126-inch reach, 18 to 24-inch gap, 80-ton capacity, boiler riveter.

BOILER TUBE CLEANERS .--- A conveniently indexed catalogue descriptive of boiler tube cleaners has been sent out by the Roto Company, Hartford, Conn. Some of the sections into which the catalogue is divided deal with cleaners for watertubes, arch tubes, fire tubes, with condenser tube cleaners, various type motors used, accessories and repair parts. Charts of savings possible with Roto cleaners and a method of computing fuel savings possible with clean tubes are included.

SHOP TROLLEYS .- A trolley folder has just been issued covering the new Yale trolleys. It is the first piece of literature to be issued on this equipment, and contains, in addition to detailed descriptions of the plain and geared types of the new Yale steel plate roller bearing trolleys, a description of the new Yale cast-iron trolleys. Incorporated in it are details of interesting tests to which the new steel plate trolley was subjected, and a complete list of the material-handling equipment manufactured by the Yale & Towne Manufacturing Company, Stamford, Conn.

STEAM DRIVEN COMPRESSORS .- The Ingersoll-Rand Company, 11 Broadway, New York, has just issued a 36-page bulletin describing "Imperial" type XPV Steam Driven Air Compressors. This compressor is built in a number of different types and sizes; standard two-stage machines for 100 pounds discharge pressure, range from 246 to 4,150 cubic feet per minute piston displacement; single-stage compressors are built for furnishing air up to 50 pounds discharge pressure. One of the outstanding features of type XPV compressors is the automatic cut-off governor.

## SELECTED BOILER PATENTS

Compiled by GEORGE A. HUTCHINSON, Patent Attorney, Washington Loan and Trust Building Washington, D. C.

Readers wishing copies of patent papers, or any further information regard-ing any patent described, should correspond with Mr. Hutchinson.

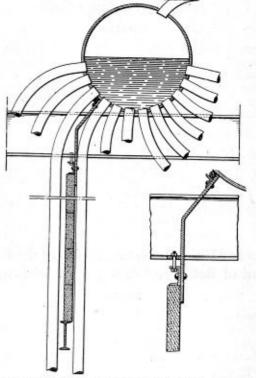

1,455,836. MEANS FOR TESTING STAY BOLTS IN BOILERS. JOHN ROGERS FLANNERY, BENJAMIN E. D. STAFFORD, AND ETHAN I. DODDS, OF PITTSBURGH, PENNSYLVANIA, ASSIGN-ORS, BY MESNE ASSIGNMENTS, TO FLANNERY BOLT COMPANY, OF PITTSBURGH, PENNSYLVANIA, A CORPORATION OF DELA-WARE.

Claim 1. The combination with a stay bolt having a bore, of a coil within said bore, a material within said bore and contacting with said coil,

said material being such as will by contact with moisture cause severance of the wire of said coil, a translating device included in circuit with said coil, and means for inducing an electric current in said coil. Three claims. 1,457,282. BAFFLE FOR WATER TUBE BOILERS. EDGAR KID-WELL, OF MILWAUKEE, WISCONSIN, ASSIGNOR TO KIDWELL BOILER COMPANY, OF MILWAUKEE, WISCONSIN, A CORPORA-TION OF WISCONSIN.

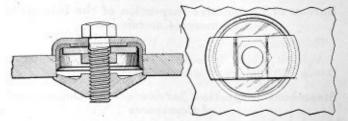

Claim 1. In a boiler of the series drum and tube type, the combination th a rearward drum and a rearward bank of water tubes extending

therefrom, of a baffle element associated with said tubes, said element com-prising a tile structure spaced below the drum and a metal member occupy-ing the space between said structure and the drum and shaped to lie in the upper curved space between adjacent rows of tubes, a rigid support below the drum, and a connection between said support and the plate mem-ber for vertically adjusting said member to force its upper edge into close contract with the opposing wall of the drum. Three claims.

1,456,314. MISSOURI. BOILER PLUG. FREDERICK E. KEY, OF ST. LOUIS,

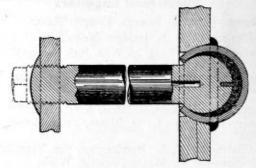

Claim 1. A boiler plug comprising an inside anchor adapted to engage the inner face of the boiler wall to which the plug is applied, a tension member secured to and extending outwardly from said inside anchor, and a closure comprising a packing holder secured to said tension member and

adapted to engage the outer face of the boiler wall, and a freely yieldable packing ring having an annular outer marginal portion secured to said packing holder and a free, flexible annular inner marginal portion con-forming to and adapted to be seated against the wall of the opening to be closed, said packing ring being exposed to receive the outward pressure of the fluid, so that the fluid pressure will force said annular marginal por-tions into engagement with their seats and at the same time place the an-chored tension member under tension. Two claims.

1,455,837. STAY BOLT STRUCTURE. JOHN ROGERS FLANNERY AND ETHAN I. DODDS, OF PITTSBURGH, PENNSYLVANIA, AS. SIGNORS, BY MESNE ASSIGNMENTS, TO FLANNERY BOLT COM-PANY, OF PITTSBURGH, PENNSYLVANIA, A CORPORATION OF DELAWARE.

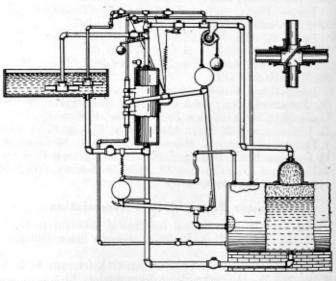

Claim 1. In a stay bolt structure, the combination with a boiler sheet having an opening of a combined bearing member and closure having an

initial universally movable mounting on the boiler sheet coincident with said opening and adapted to permanently enclose the head of a staybolt, staybolt having a head mounted in said member, and a weld securing said combined bearing member and closure to the boiler sheet. Two claims.

1,456,722. BOILER-FEED WATER SYSTEM. GEORGE W. COPE, OF OIL CITY, LOUISIANA.

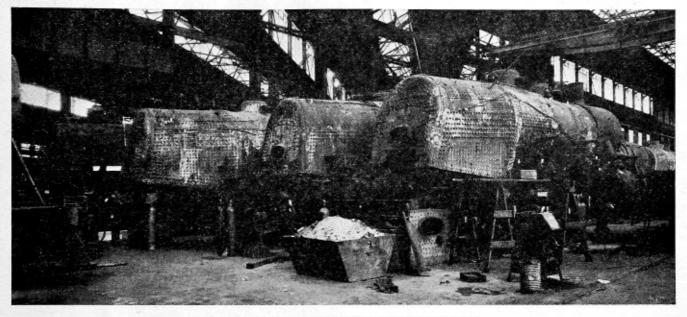

Claim 1. In a gravity feed water system for steam boilers having a charging tank, said tank situated above the boiler water level and having a valved water inlet and a valved water connection with the boiler's water

space and having valved steam connections with the steam space of the boiler, an air inlet and outlet and a valved steam outlet combined with means for operating the valves of said valved steam inlet and outlet means for gradually establishing boiler pressure upon the water in said tank to thereby prevent the high speed flow of a large volume of steam upon the water in said tank and prevent a water hammer, said means comprising essentially a primary steam inlet, a valve in said primary steam inlet, means connecting the valve with the valve operating means, a secondary steam inlet, a valve in said secondary steam inlet, and an elastic connection connecting the valve of the secondary steam inlet with the valve operating means. - Seven claims.

Battery of Boilers on Special Trestles for Repair

## Repairing Locomotives in a Contract Shop

OLLOWING the war, the Morgan Engineering Company, manufacturers of overhead cranes and other heavy mill equipment at Alliance, Ohio, found itself with a large plant unequipped except with cranes, that had been built for the manufacture of heavy ordnance. The demand for outside capacity for heavy locomotive repairs, which developed after the drastic curtailment of mechanical department forces on the railroads in 1921, led to con-

The extensive locomotive repair program of the present year has made it necessary for many railroads to send heavy repairs beyond the capacity of their facilities to contract shops having the equipment and organization for carrying on such work. The following article outlines the methods employed by one contract repair shop that was built up around a war-time ordnance plant. Special emphasis is placed on the type of boiler repairs handled and the special methods employed for boiler work.

840 feet long by 90 feet wide, from one side of which opens a series of parallel bays extending out at an angle of about 34 degrees from the header bay. As these bays all terminate in a single end wall, they vary in length from about 115 feet in the case of the short bay opening into the header bay nearest its southern end to about 530 feet for the east bay opening from the north end of header bay. The building is of steel frame construction with brick curtain walls at

sideration of the utilization of this plant as a contract locomotive repair shop. Accordingly, after a satisfactory form of contract had been worked out, which required the development of a base sufficiently detailed to cover all usually performed operations while still retaining a degree of flexibility which would take care of all work the need for which becomes evident only after a locomotive has been stripped, an organization was developed and operations started.

## LAYOUT AND ARRANGEMENT OF PLANT

The first engines were repaired during the latter part of 1921. Owing to unsettled conditions, however, operations did not actively get under way until the fall of 1922.

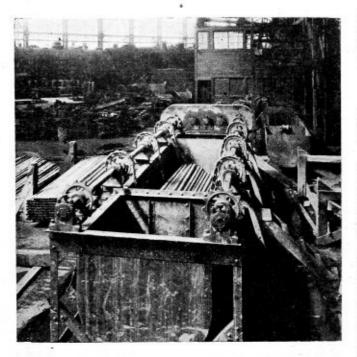

The building consists of what may be termed a header bay

the lower portion of the sides of the building, above which there is an unbroken expanse of steel sash. Additional light is admitted through glazed openings in the roof.

This building is located in an enclosure adjoining the south end of the main plant yard, in which its manufacturing operations are conducted. The two enclosures are separated by a street, but communication is maintained between them by continuous industrial tracks and by the plant roadways, over which material is transported to and from the locomotive shop by motor truck.

### FEATURES OF THE ERECTING SHOP

The most interesting feature of the locomotive repair shop is the method of handling erecting shop work. The erecting

Small Tubes Being Cleaned in Wet Rattler

shop occupies the long bay from which open the parallel bays and has floor space for 70 locomotives in addition to those on the stripping and wheeling tracks. This building originally was not equipped with pits and had but two tracks running through it, one along either side. With practically no changes in the floor construction it has been adapted to effective use as a locomotive erecting shop by the portable structural steel stools on which the locomotives are supported. These are of sufficient height to permit work to be done under the engines after they have been stripped and placed on their "spots" without the necessity of floor depressions and with better lighting under the locomotives than normally found where they are set over pits.

The only change in this shop has been the construction of pits along the track on the side from which the parallel bays open, which is used as a wheeling and finishing track. As will be seen from the illustrations, the locomotives are placed on their spots in a staggered formation so that the tubes may be removed from the front end of one locomotive without interference from the locomotive next in front of it.

### ARRANGEMENT OF BOILER TEST BLOCKS

At the north end of the erecting bay is what is known as the testing block. Here the first spot in each of the four rows between the stripping and wheeling tracks, is devoted to the making of hydrostatic tests.

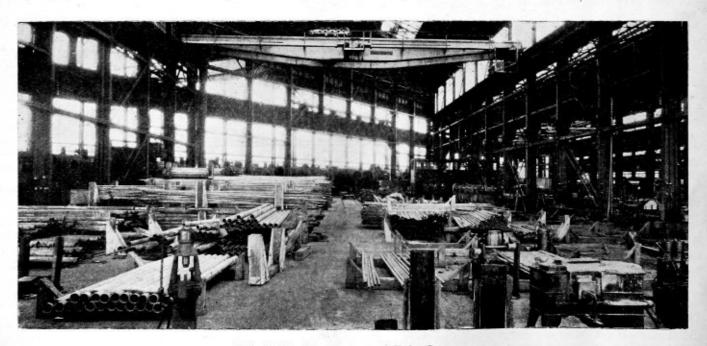

The erecting bay is served by three Morgan cranes, all operating on the same ways. The capacity of the first toward the south end of the shop is 75 tons, of the next, 40 tons, and of that toward the south end of the shop, 25 tons. Slings are used at both ends of the locomotives when lifting with the cranes. In moving a locomotive about the shop, the sling from the 75-ton crane is placed around the barrel of the boiler just ahead of the firebox, while the 40-ton crane lifts the front end. The stripping track accommodates six locomotives. Here the engines are completely stripped, the parts removed to the lye vat, cleaned and delivered to the machine shop by the stripping gang. After stripping, the locomotive is unwheeled and moved to the "spot" assigned to it, where the boiler, frame and cylinder work is done. When ready to be assembled, the boiler and frames are moved by crane to the wheeling track and from here through the several assembly operations until the locomotive has been tested and accepted.

#### BOILER SHOP AND EQUIPMENT

A series of bays opening into the erecting shop is arranged to accommodate the various repair departments. Like the erecting shop, each of these bays is well equipped with overhead cranes, and a comparatively small amount of special equipment has been installed.

Starting at the south end of the erecting shop, the first of these bays is occupied by the flanging department. This bay is served by one 40-ton crane and is equipped with an annealing furnace, three open fires and one hand and one pneumatic flanging clamp.

The next bay is occupied by the flue shop, the arrangement of which is shown in one of the illustrations. This bay is served by one 10-ton and one 40-ton overhead crane, and is equipped with three welding sets, each consisting of a

Draper hammer and a Ferguson furnace. One of these is used on superheater flues and the other two on tubes. These facilities are arranged along the south wall of the bay. Two flue rattlers of the wet type have been placed on the shop floor at the east side of the bay near the erecting shop, one of which can be loaded and unloaded by crane, while the other requires manual loading. The flues are tested under 100 pounds air pressure, submerged in water.

### TUBES STORED IN SETS

Owing to the practice of the Morgan Engineering Company of taking in as many locomotives as the available erecting floor space will permit, irrespective of the number on which work is actually being performed, a large number of sets of tubes are stored in the flue shop. Instead of progressing from one operation to another with no intermediate handling, the practice is to complete each operation on each set of tubes, after which the entire set is moved by crane to the station of the next operation.

The outer end of the third bay is occupied by the boiler shop for laying out firebox sheets. The remainder of the bay is devoted to the repair of detail fittings. On the west side are located a battery of six small engine lathes, a small shaper and one Lassiter-Milholland staybolt machine. The latter machine gives an output of 350 staybolts, turned and threaded, in 12 hours. This bay is served by one 10 and one 25-ton crane, the heavier crane being located toward the erecting shop end.

The next bay to the east, which is approximately 90 feet wide, is devoted to heavy boiler work. Here the work on all boilers requiring new fireboxes or back ends is completed before the boilers are returned to the erecting shop. This department is provided with one vertical and one horizontal punch, a vertical shear and a radial drill for drilling tube sheets. The shop is not equipped with a heavy bending roll and all firebox or boiler shell sheets requiring bending are sent outside. On the east side of this bay is located a testing block for superheater units. Here all units are tested and inspected as they are removed from the locomotive, to locate those requiring renewal. After the units have passed this test, they are stored in sets in the next bay, so piled that all header joints are accessible. The joints are ground with a portable machine as they lay in the pile.

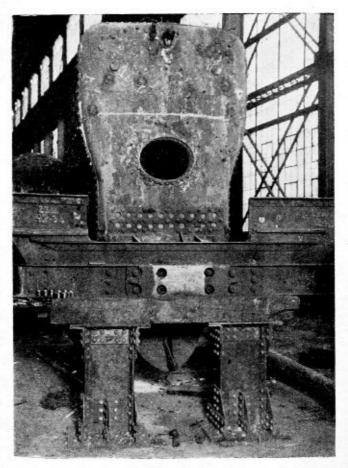

The outside bay is about 50 feet wide. It is devoted to engine truck repairs, cabs, and superheater unit storage. Space is also provided in this bay, just off the erecting shop, for lagging storage and reclamation. No provision is made for remolding broken lagging. Broken material is pulverized and tempered for bulk use in plastic form.

This bay, which is equipped with two 10-ton cranes, was formerly used as a tender repair shop. This work, however, has now been transferred to one of the buildings in the manufacturing plant, which was formerly occupied by the iron foundry.

#### DETAILS OF BOILER REPAIR WORK

When a boiler requires a new firebox it is brought into the bay devoted to boiler work where the firebox is laid out, punched and sheared, flanged, fitted and applied to the boiler. All staybolts and crownbolts are applied in this bay, in fact the boiler is completed with the exception of installing the flues.

As work is carried out at the plant for about ten different railroads, it is impossible to standardize the methods of performing firebox repairs. Such work must be done in accordance with the various standards of the railroads with which the plant has contracts. All welding on the fireboxes, however, is done by the electric arc process. On some fireboxes, for example, the railroads specify that the welding be done on the inside and reinforced on the outside. Other roads specify that the firebox be welded complete, while still

Special Type Trestle for Carrying Boilers During Repair

others require that the door sheet and back flue sheet be refitted with the exception of the waterlegs which are welded.

Some railroads have the flues electric welded in the firebox, others have the superheater flues, and the small flues between, welded in both ends. Others do not have the flues welded until after the engines have been in service for some time. The flues are all electric welded on the assembly track.

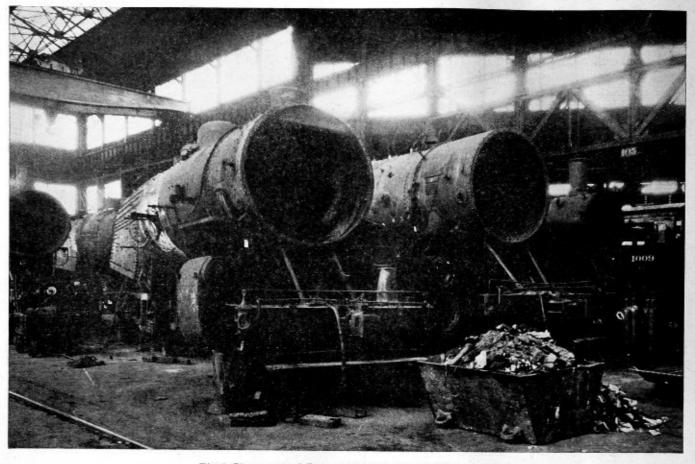

In removing flues a motor attachment has been developed for cutting the flues in the front flue sheet. Where a new back flue sheet is required, a section of it is taken out and the flues removed through this hole.

Flanged work is all done by hand, as each railroad having work done in the shop uses different types of boilers and since there are so many different types on a single order it is not practical to make dies to press out flue sheets and door sheets. A special rig used in drilling staybolts utilizes a counterweight attachment for raising and lowering the motor and also for raising and lowering a plank which acts as an "old-man." One man with this rigging is able to drill an average of 60 bolts an hour.

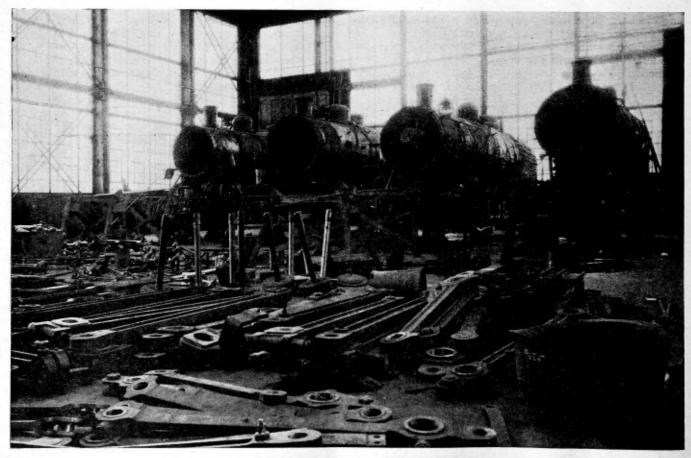

### SUMMARY OF WORK PERFORMED IN THE BOILER DEPARTMENT

On one order of 30 Mikados which has been in the shop for a comparatively short time, 20 have already been rebuilt. The boiler repairs on these locomotives call for new back flue sheets, 3/4 door sheets, 3/4 back heads, 3/4 inside side sheets. These boilers have been changed from hand fired to stoker fired and a complete installation of flexible staybolts made.

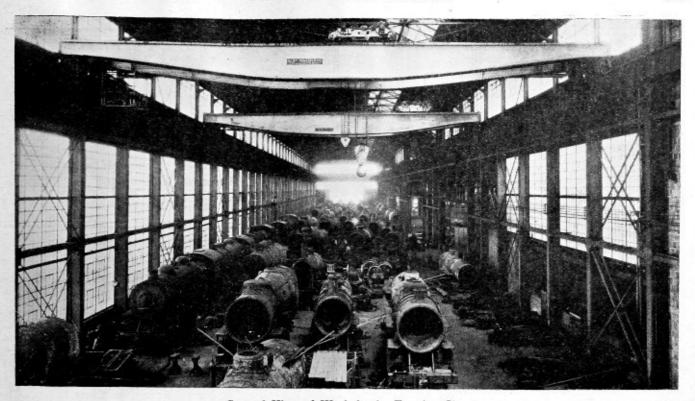

The firebox on this type of Mikado is 75¼ inches wide and 108¼ inches in length having a grate area of 56.5 square feet. The firebox has a heating surface of 230 square feet. The boiler contains two hundred and fifty-seven 2-inch

Final Clean-up and Boiler Assembly in Erecting Shop

A Final Test Under Steam is Given the Locomotives in this Department

General View of Work in the Erecting Shop

flues and thirty-six superheater flues  $5\frac{3}{8}$  inches in diameter. The 2-inch flues have a heating surface of 2,745 square feet and the superheater flues, a surface of 1,033 square feet, making a total heating surface of 4,008 square feet. The total weight of the engine is 287,000 pounds not including the tender. The tender, loaded, weighs 153,900 pounds in addition.

On another order of 10 Mikados, the fireboxes have been installed complete with combustion chambers. These locomotives have a tractive power of 60,800 pounds. The weight of the engine, not including the tender, is 322,500 pounds. The tender weighs 168,900 pounds, the total weight of engine and tender being 491,400 pounds; the firebox has a heating surface of 283 square feet; the heating surface of the tubes is 3,768 square feet; the superheater heating surface is 845 square feet or a total heating surface of 4,051 square feet with an equivalent heating surface of 5,318 square feet. The firebox is  $84\frac{1}{4}$  inches by  $114\frac{1}{8}$  inches. The combustion chamber is 20 inches by 80 inches diameter with a grate area of 66 square feet. The boiler barrel is 96 inches in diameter.

Several engines of the consolidated type and the Pacific type have been converted from coal to oil burners in addition to changes in the boiler which necessitated a complete change and rearrangement of tenders.

#### INSPECTION DEPARTMENT

Each railroad has its own inspection organization and both the Morgan Engineering Company and the railroad's inspectors are provided with complete sets of drawings of the locomotives passing through the shop. Much of the material, particularly brass and iron castings and all special fittings are furnished by the railroads. Each railroad is provided with its own storehouse in charge of its own storekeeper, these stores being housed in small buildings of frame construction adjoining the south wall of the parallel bays.

#### SHOP ORGANIZATION

. To a large extent the employees engaged in the locomotive repair work, aside from those in the manufacturing department, are semi-skilled men rather than fully qualified mechanics. The work is therefore specialized in all departments under the jurisdiction of the superintendent of the locomotive repair department.

In the erecting shop most of the gangs are small and highly specialized, working under gang leaders. All welding and cutting work is handled by one gang which is in charge of a foreman. The same organization idea is carried throughout the plant. In the case of the boiler department about 80 percent of the men are semi-skilled specialists. In this department one gang does nothing but remove sheets which are to be renewed. The sheets are then taken to the laying out department where new ones are laid out, punched, sheared and made ready for the fitters. The fitting gang then assembles the sheets ready for the welders and riveters. The welding is performed first, after which the remaining joints are riveted and calked. The staybolts are then applied followed by the crownbolts, each operation being performed by a separate gang.

The boiler is then sent to the test block and washed out and the flues applied after which it is given the hydrostatic test. It is then taken to its specified spot on the erecting floor where a miscellaneous gang cleans up any work that develops as a result of the test. The testing block gang takes care of all boiler work which develops during the running tests after the locomotive has left the shop.

During the month of June there was an average of about 1,000 men actually working on locomotive repairs approximately 250 of which were boiler makers and helpers, 300 were employed in machine and forge departments and 450 on the erecting floor on air brake repairs and in the tank shop. From 725 to 750 of these men were located in the departments housed in the locomotive shop building.

During the month of June the output was 36 locomotives, none of which required less than Class-3 repairs, many of them running very heavy. Of the 40 engines completed during the month of July, two required complete new back ends; 7 required new fireboxes; 20 required new back tube sheets, door sheets and inside side sheets, the remaining 11 called for either new back flue sheets or new side sheets and patches.

## Boiler Inspection Work In Malaya

By George Cecil

THERE are pleasanter spots than the Malay Peninsula, or the Federated Malay States, as it is known officially, in which to earn one's living as a boiler inspector, for the muggy, sultry climate is ever trying, even in the (reputed) "cold weather," and there is little of that light and agreeable side of life which awaits the white man in other British colonies. True, the mountain sanatorium is at the disposal of those who, rendered liverish and run-down by days and nights of sweltering heat need a change. There the exile breathes the finest air in all the world, and roses, grown in the hotel garden, adorning the vases on the dining room table, gladden his sight at breakfast time.

But the "hills," alas, only are for the well-to-do; for prosperous merchants and highly-paid officials, who are provided by the British government with employment which takes them a few thousand feet above sea level. The boiler inspector remains "down below," as the "plains," are termed, his work keeping him there month in and month out. He is granted periodical leave of absence, being entitled to thirty days a year, and he is treated generously enough where sick leave is concerned. The unfortunate man's pay is, however, comparatively small, seldom can he afford to sample the mountains. His means only admit of a short sea voyage to perhaps Calcutta or Rangoon, and a sea voyage in the heat of the Indian Ocean has its disadvantages. Only in the monsoon season is the air at all cool, and that lasts but a few weeks; besides, there are frightful storms-none more devastating. The invalid may find himself in Davey Jones' locker.

#### RETIRED ON PENSION

Yet the expatriated one might be worse off. Being a government servant he is entitled to a pension after some twentyfive years' service in the sweltering Federated Malay States.

Not a large pension, little more, in fact, than a decent competence. He draws his pay with clock work regularity on the first of each month, and the traveling allowances are based on a scale which leaves a margin of profit. Indeed, a boiler inspector who lately retired admitted that disagreeable though he had found his tours of inspection, they had enabled him to put by something worth having in way of a nest egg. Having long outgrown his original hankering to take leave "Home" (all well-regulated exiles speak of England as "Home"), the pensioner leads a contented life in a mountain bungalow, taking in "paying guests" and turning a pretty penny over this commercial hospitality. Scotch is he!

Another retired boiler inspector, who enjoys a ripe old age, is to be found in Malacca. Having left England some fifty years ago, without once returning to his almost forgotten native land, and being acclimatized, the exile asks nothing better than to spend his declining years where he is. Speaking the vernacular like a native, he is more Malay than English.

### AN UNDESIRABLE CANDIDATE

The natives, as in other colonies, see no reason why they should not oust the imported white boiler inspector. "It is," they plaintively state, "admitted that we are intelligent. Show us how a thing should be done and we are capable of doing it. We act as oilers wherever machinery is employed and some of us have even been promoted to the part of assistant engineer. Why then, in the name of the Great Spirit, withhold from us a coveted post which carries with it monthly pay, various emoluments, and a retiring pension?" Decidedly an eloquent statement of the case, and one which might appeal to those who have not met the Malay at close quarters. Unfortunately, he is-though intelligent-the essence of laziness and casualness, and, at times, quick tempered, drawing a murderous kriss, which he introduces, without compunction, between the shoulder blades of the tuan bessar (European) who has cause to reprimand him. The

Buffalo Carts are Used by the Inspector for Transport

yellow man also is a confirmed taker of bribes, looking upon their acceptance as part and parcel of the business of life. Were the Malay to be entrusted with the inspecting of a boiler, he would—well, yield to bias. The government turns a deaf ear to his prayers.

The Chinese element (the Peninsula is full of "Chinks") also puts in a claim, based on much the same grounds, while the semi-Chinee—semi-Malay has aspirations in this direction. So, too, have the sons of European fathers and colored mothers, each passionately arguing his fitness for the coveted post. These applications are ruthlessly turned down, the powers-that-be deciding that boiler inspecting is best entrusted to the unadulterated white man. The disappointed candidates, airing their views in the "Utusan Malayu" ("Malay Herald") and other vernacular newspapers, declare that the government is composed of tyrants compared with whom Nero was an enlightened philanthropist. The editor supports them in a ferocious leader, and those who have snowed up the native press, resting on their literary oars, await developments. They still are waiting.

To satisfy the malcontents, a few appointments have been temporarily given to Malays and half-castes—and with disappointing results. None of these specially-appointed boiler inspectors have justified the trust reposed in them. Inherent laziness and other failings have proved their downfall.

## BULLOCK CART TRANSPORT

Except in the towns, there is little work for the boiler inspector. Several heated days may pass by without a "job of work" being assigned him. When, however, he is sent into the district, covering a long journey by pony, river boat, and perhaps by a jolting bullock cart over a road which is all ruts and holes, the much-tried man certainly has earned his day's pay and traveling allowances. If the boiler in-spector is no horseman, the bullock cart may be the only alternative. Drawn by two cross-grained animals, who, should the humor seize them, calmly sit down till the driver's goad succeeds in making an impression on their extra-tough hides, the rate of progress is limited to rather less than three miles an hour. When no government "rest house" is handy, the boiler inspector must sleep in the bullock cart, the thatched roof of which keeps off the night dew. A mosquito net protects the sleeper against the pestiferous insects, and, should he awake in the night with a raging thirst, a huge water bottle packed in damped grass is at his disposal. The mosquito net is arranged so as to cover the space occupied by the bottle. Raise the extremity of the tucked-in net but a quarter of an inch, and in pop the buzzing tormentors-ready to goad the rash inmate into a state of frenzy. He thanks his lucky stars when fiery sunrise drives away these pests.

In default of a "rest house" the boiler inspector may find accommodation of a primitive nature in a wayside village. The headman, greatly impressed at seeing a white face, provides the *tuan bessar* with a primitive bed, across which a net work of fiber is stretched. A supper of freshly-caught fish (tasteless and abnormally bony), rice (cooked to perfection), and roasted bananas, is served, the villagers respectfully looking on while the grateful boiler inspector makes short work of the victuals. The next day the guest, after settling the score, expresses his sense of indebtedness, and politely hopes that all will ever be well with the village. "We ask nothing better," chorus the villagers, "than to be blessed with a good rice crop. Pray intercede on our behalf with the Great Spirit!" The intercession is promised, and the bullock cart once more creaks its weary and laborious way over the interminable ruts. A rough road,—none rougher.

The boiler inspector is not always so lucky as to light upon a friendly host, it sometimes happens that the Malay, craftily watching his opportunity, whips out the *kriss*, and, helping himself to the victim's note case and other possessions, deposits the corpse in the jungle. A tiger devours it; the driver of the bullock cart is informed that the white man, greatly daring, has sought the wild beast in its lair; and there is promotion in the ranks of boiler inspectors. Sometimes an inquiry brings the offenders to book; their guilt is proved right up to the hilt; they are hung as high as Haman.

In Singapore the boiler inspector may be kept busy. Steamers with doubtful boilers are ever coming and going, many of these craft being owned by Chinese firms, which, at-

### The Traveling Boiler Inspector Stops at Such Places for Refreshment

taching no importance to human life, are not particular as to the state of the boilers. So ancient and decrepit are some of these boilers, with their thin, rusted plates, that a white fireman would refuse to sail with them. Fortunately for the owners, a "Chink" fireman is far too great a fatalist to be worried by trifles. "One must die," he argues. "Has not Buddha willed it? Dare a Buddhist go against the ruling of Buddha?" So the Chinaman is ready to face death by scalding.

The railway terminus also affords employment for the boiler inspector; and his duties include periodical visits to the ship repairing yards, as well as to various concerns where boilers are in use. At the end of a sweated day he is glad of a long cane-bottomed chair, in the shady veranda of his bungalow, a Manila cheroot and a *stringer* peg (iced whiskey and soda). The perspiring man has earned these luxuries.

## New Boiler Law in Pennsylvania

TWO laws pertaining to the collection of fees for services rendered by the Department of Labor and Industry, Commonwealth of Pennsylvania in the administration

of the rules and regulations of the department covering boilers and elevators were passed at the last session of the legislature.

The Boiler Law provides for the inspection of boilers by representatives of insurance companies and by salaried employees of the Department of Labor and Industry. Owners and users of boilers will be required to forward to the Department of Labor and Industry a fee of one dollar before the annual certificate of operation for the boiler will be issued.

When boilers are inspected by representatives of the Department of Labor and Industry a fee of six dollars and fifty cents (\$6.50) will be collected for each external and internal inspection made while the boiler is not under pressure, and two dollars and fifty cents (\$2.50) for external inspection made when the boiler is under pressure.

### EXAMINATION FOR INSPECTORS

Persons desiring to take examination for boiler inspector are required to pay a fee of ten dollars (\$10.00) at the time of making application for examination. If the applicant is successful in passing the examination a certificate of competency and a commission card will be issued without further charge.

It is the plan of the Department to put this law into effect as soon as the necessary forms can be printed.

## Methods of Applying Flues in Locomotive Boilers*

This report, which was read at the annual meeting of the Master Boiler Makers' Association held at Detroit, May 23 to 26, was compiled from the flue practice of the more important railroads of the country. It includes details of how flue ends should be prepared, the manner of preparing holes in the tube sheets, the type and size of copper ferrules to be used and the method of tightening flues in the sheets, as well as the standard tools for rolling, prossering and beading flues.

A FTER checking up the methods of various railroads, it is believed that for a two inch diameter flue, flues should be swedged 134 inches diameter for a distance of seven-eighths of an inch straight, then tapered back to nothing for a distance of 31% inches. This is far superior to a flue swedged 17% inches diameter straight for one inch, with a taper of one-quarter to its original diameter, to provide increased water space, for it is a well recognized fact that the first few inches of the flue measured from the flue sheet, is the most efficient heating surface. This increased water space allows the steam bubbles to form and pass up between flues unrestricted. If it is not provided, the bubbles are

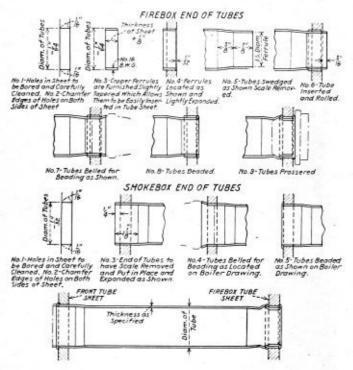

Fig. 1

trapped between the flues and drive the water away from the flue sheet. This causes the flue sheet and flue ends to overheat. This is one of the best known methods of shortening the life of flues. After being swedged flues should be annealed and care taken to see that all scale is removed from that part of the flue which is to enter the sheet, for it is a well known fact that we are unable to get tight flues with scale or any dirty substance between the copper ferrule and flue.

The swedging of superheater flues seems to be the general practice on all our railroads, the swedge being of the following dimensions: In  $5\frac{1}{2}$ -inch outside diameter flues,  $4\frac{1}{2}$  inches outside diameter,  $5\frac{1}{8}$  inches straight, tapering to the  $5\frac{1}{2}$ -inch diameter, three inches back; flues to be prepared as to the removal of scale the same as on smaller flues.

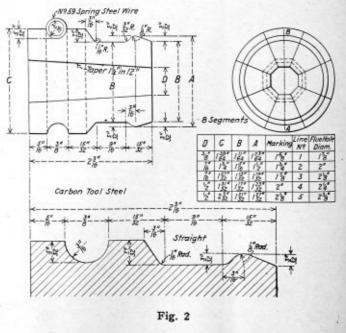

*Report prepared by a committee consisting of A. F. Stiglmeier, chairman; E. C. Umlauf and James F. Walsh.

### PREPARATION OF FLUES FOR INSTALLATION

The preparing of flues, both small and superheater for the front tube sheet, seems to lie between the practice of shimming the same with tin, or expanding to fit the hole. Expanding should be done before the flue leaves the flue department, for good results can be obtained when heated properly, for there are many simple ways that are not harmful to flues. In shimming flue with tin, there is a possible chance that when the boiler maker applies the shim he will not get it through the sheet, so that it may blow out, causing a failure besides possible damage.

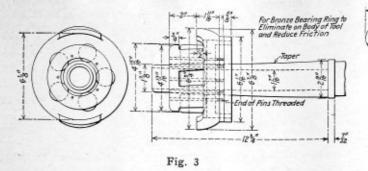

Drilling flue holes in the back flue sheet will have to be governed by the diameter of the swedge and copper ferrule used. The committee recommends that all flue holes in back flue sheet have inside and outside edges slightly rounded, to remove the sharp edges, the radius to be about 1/16 of an inch. Flue holes in old back flue sheet should be examined for sharp edges, rust and scale and the same removed. Holes 1/32 inch or more out of round, should be reamed. In this you will readily see the advantages of a  $1\frac{3}{4}$ -inch diameter swedge over a larger size. The smaller flue hole will give increased bridge strength between the flues, and at this time, when it seems to be the general practice on most of the railroads to electric weld the beads of flues to the back flue sheet, a greater space is required between the flue beads. If not provided, the electric welds will over-lap each other, which is not a good practice.

Drilling holes in the front flue sheet seems to be a general practice as to the diameter on all our railroads. The committee recommends that all holes drilled for flues smaller than superheater be 1/16 of an inch larger than the outside diameter of flues, and for superheater flues three thirtyseconds larger than the outside diameter of flues. Holes

31

252

should be prepared the same as for back flue sheet, by removing the sharp edges from the inside and outside of sheet.

## COPPER FERRULES USED

The committee recommends a copper ferrule 1/16-inch. (0.065 thick), by 1/8 inch over the thickness of flue sheet for the width for both small and superheater flues, ferrules to be of soft, seamless copper, annealed. While many railroads are using a copper ferrule of the same width as the thickness of sheet, the committee believes this to be too narrow, as the function of a copper liner is to provide a yielding medium between the flue and the sheet, so that the flue will take a light, permanent set when expanded. It is just as important that the soft medium be applied between the bead formed by the sectional expanders on the inner edge of flue hole, as between the flue and flue hole. The committee recommends that sectional expanders be used to apply copper ferrules and great care be taken that the ferrule is set 1/32 inch inside of the edge of hole on the fire side of sheet. This is of great importance because if it is left even with the fire side of the sheet there is a possible chance that when the flue is expanded the ferrule will project outside the fire side of the sheet, and after being beaded it will work itself outside of the edge of the bead. This we all know will not do on flues that are to have beads electric welded to the back flue sheet, for it is a well-known fact that copper will not mix with the electrodes used in welding.

The committee further recommends that flues smaller than superheater project through back flue sheets 3/16 inch for beading. When a small flue is to be beaded at the front flue sheet 3/16 inch is to project through the sheet; when it is not to be beaded the minimum is to be 3/16 inch and the

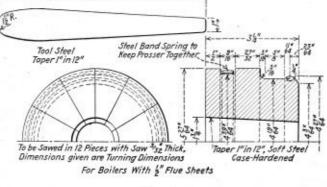

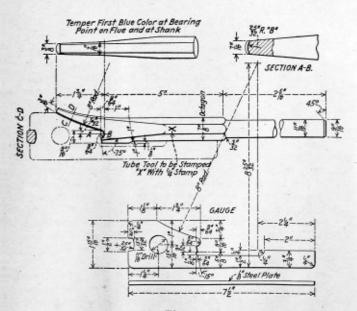

Fig. 5

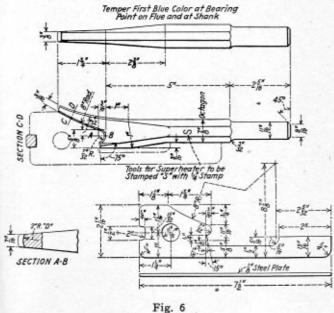

maximum  $\frac{1}{2}$  inch. Superheater tubes are to project through the back flue sheet one-quarter of an inch, and one-quarter of an inch to be used on front flue sheet when flues are to be beaded. When superheater flues are not to be beaded at the front end, the minimum and maximum length for flue to project through flue sheet is to be the same as small flues.

## TIGHTENING FLUES IN SHEET

Tightening of flues in the back flue sheet seems to be quite a delicate subject, for checking up the methods of the various railroads shows a leaning toward the use of the sectional expanders to tighten flues. The committee does not care to recommend it, but does recommend that roller expanders be used in the firebox end as well as the front end to tighten flues. The chairman has made a test of both and finds that the sectional expander does the flue harm, as sectional expanders have to be turned two or three times. The first time the pin is driven into them a small space between each section is not expanded. This is where the harm occurs, as flues are checked at this point, but it cannot be noticed. After they are electric welded the heat will open up the checks and develop leaks, after running a short time. These conditions also exist in flues that are not electric welded at the bead after being in service. Such conditions will not exist on flues that have been tightened in the sheet with roller expanders, which give equality of expansion. The committee recommends that after flues are tightening in the

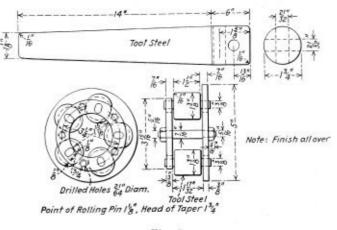

Fig. 7

back flue sheet, sectional expanders be used to expand them inside of the sheet. They are then to be rolled in the front end. Flues should not be beaded at the front or back end until after the boiler is tested. Investigation of different cases of leaking flues has shown that by the other method of testing leaking flues may be covered up. If a flue tested before being beaded shows no leak it will not developed a leak after being in service a short while.

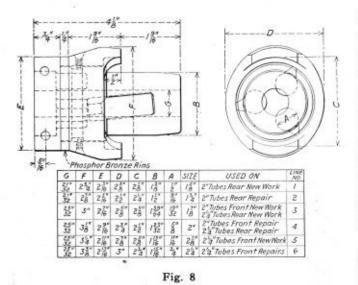

Figs. 1 to 8 inclusive show sketches of standard tools for rolling, prossering and beading tools, as well as various operations incident to flue installation.

The committee also recommends that a flue roller should never, under any circumstances, be used in a flue after it has been expanded with a sectional expander. It will stretch the metal and break the joint made by the sectional expander and beading tool.

#### APPLYING FLUES IN STATIONARY BOILERS

As to the application of flues to stationary boilers, the chairman corresponded with various boiler manufacturers and among replies received were the following:

"In applying flues to water leg type of watertube boiler, using four inch tube expanded into one-half inch plate in each boiler leg, we first roll the tube in position with three parallel rolls; then take out one of the rolls and put in a roll designed to bell the end of the tube which extends into the water leg. The tube end is thus belled or flared to comply with the A.S.M.E. Boiler Code. We are now experimenting with another type of expander body and have had

good results, so far. This body has three rolls, two of which are slightly tapered so that the surface of the tube as rolled will be parallel to the axis of the tube—in other words, the outside edge of the rolls, where it comes in contact with the tube, is exactly at right angles to the tube sheet. The other roll in this new type of expander is designed to bell or flare the end of the tubes, thus the rolling and flaring is done at the same time."

## TOOLS FOR EXPANDING AND WORKING FLUES IN STATIONARY BOILERS

"In answer to your inquiry we are attaching herewith two prints showing general type of tools used in expanding the ends of tubes in Heine boilers. The sheet which contains a picture of a Heine boiler also shows the general type of tool which is used by power plants for the renewal of individual tubes when it becomes necessary. The other print shows the general type of expander used in the shop. You will note that this latter tool is more elaborate in that it has a collar which acts as a guide for the mandrel as well as to take the thrust caused by the rollers when the mandrel is driven in place. In Heine boilers it is not required that the ends of the tubes be beaded, but it is necessary to flare them. The American Society of Mechanical Engineers Boiler Code,

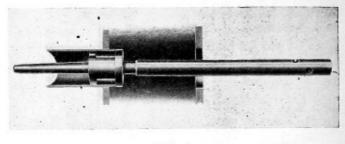

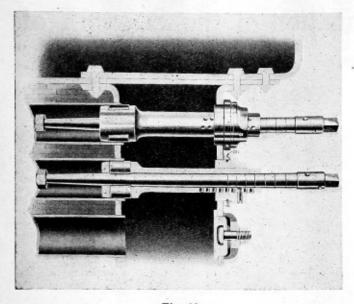

Fig. 9

under which we construct most of our boilers, calls for the tube ends to be flared to at least one-eighth inch over the diameter of the tube hole. Ordinary roller expanders have a tendency to slightly flare the projecting ends when the rolling is done, but a slight additional flare is provided by driving a conical piece into the tube end holes, spreading it the required amount. One or two licks of a comparatively heavy hammer will do this flaring without loosening the tube where it has been rolled."

Tools for stationary boiler tubes are shown in Figs. 9 and 10.

"The great majority of boilers we manufacture are of the fire tube type for stationary purposes. It has always been our custom to use a prosser expander for putting tubes in fire tube boilers; after the tubes have been expanded by means of the prosser we bead the tube against the sheet. We allow 1/64 inch clearance between tube and sheet. Some times we are requested to provide the rear tube sheet with copper ferrules. Where copper ferrules are used we follow the same procedure and use the prosser expander. Some manufacturers simply roll the tubes in the sheet, but we do not consider it good practice as we feel that in a fire tube type of boiler the tube is acting more or less as a stay and by expanding the tube by means of a prosser expander that portion of the tube expanded inside the tube plate acts more or less as a lock nut would act on a stay rod. In building boilers of the watertube type we, of course, roll the tube and after rolling flare the end of the tube."

"1. Tubes for stationary watertube, and flues for fire tube steam boilers shall conform as to specifications of manufacture and thickness to the following instructions and shall be requisitioned in accordance therewith.

"2. Tubes for stationary watertube steam boilers shall conform to Department of Tests' Specification, and thickness shall be as follows:

- (a) Up to but not exceeding 165 pounds per square inch for tubes of Diameter less than 3 inches. No. 12, B. W. G.—0.109 inch thick. Diameter 3 inches or over, but less than 4 inches No. 11, B. W. G.—0.120 inch thick. Diameter 4 inches or over, but less than 5 inches No. 10, B. W. G.—0.134 inch thick.
- (b) Over 165 pounds per square inch but not exceeding 235 pounds per square inch for tubes of Diameter less than 3 inches No. 11, B. W. G.— 0.120 inch thick.

Diameter 3 inches or over, but less than 4 inches No. 10, B. W. G.-0.134 inch thick.

Diameter 4 inches or over, but less than 5 inches No. 9, B. W. G .--- 0.148 inch thick.

Note—For (a) and (b) above next heavier gage than that indicated for each respective pressure may be used for those tubes which are directly over the fire such as the first and second rows of tubes in B. & W. boilers, etc.

"3. Flues for stationary fire tube steam boilers shall conform to Department of Tests' Specification and thickness shall be as follows:

- (a) Up to 175 pounds per square inch for tubes of Diameter less than 2¹/₂ inches No. 13, B. W. G.—0.095 inch thick.
  Diameter 2¹/₂ inches or over, but less than 3¹/₄ inches No. 12, B. W. G.—0.109 inch thick.
  Diameter 3¹/₄ inches or over, but less than 4 inches No. 11, B. W. G.—0.120 inch thick.
  Diameter 4 inches or over, but less than 5 inches No. 10, B. W. G.—0.134 inch thick.
- (b) Over 175 pounds per square inch but not exceeding 250 pounds per square inch for tubes of Diameter less than 2½ inches No. 12, B. W. G.— 0.109 inch thick.

Diameter  $2\frac{1}{2}$  inches or over, but less than  $3\frac{1}{4}$  inches No. 11, B. W. G.—0.120 inch thick. Diameter  $3\frac{1}{4}$  inches or over, but less than 4 inches

No. 10, B. W. G.-0.134 inch thick.

Diameter 4 inches or over, but less than 5 inches No. 9, B. W. G.-0.145 inch thick.

## **Responsibility for Boiler Equipment**

A RECENT letter to members of the American Boiler Manufacturers' Association, sent out by the secretary, H. N. Covell, calls for an expression of opinion on the subject of the difficulties that the manufacturer sometimes has with back charges for boiler fittings and equipment. The letter is given below for the information of the industry. The secretary will be glad to hear from members and forward a report of the replies to those interested.

"There is a source of annoyance and expense to which we have been subjected in recent months to such an extent that we are compelled to seek some remedy, and are addressing you in the hope that you may be able to present our case to the members of the A. B. M. A. and obtain an expression as to whether they are having similar troubles, and if so, what their general attitude is. We refer to back charges of the class outlined below made by

the customer: 1. Reported shortages of fittings or small castings, which are

later found in some corner or under some rubbish, usually after the replaced part has been rushed forward by prepaid express.

 Broken castings and other damaged items which are accepted from the railroad company by the customer without proper notation of such damage having been made on the bill of lading.

 Damage caused by careless unloading and by careless handling on the part of truckmen and riggers.

4. It has been our policy to consider the customer first and to do everything to get his equipment operating, and then discuss the question of responsibility.

Recently however, so many cases have come up where the blame could not by any stretch of imagination be laid at our door, and still the customer has flatly refused to accept any responsibility. We cannot teel that this is a condition peculiar to ourselves and if

We cannot feel that this is a condition peculiar to ourselves and if it is not, we would certainly appreciate an expression from some of our fellow members as to their method of handling similar situations.

If this condition is as prevalent in other fields as in our own, it would seem advisable for our members to adopt a general policy for their own protection and such a policy if adopted by even the majority of our members would certainly be of tremendous advantage.

Of course, we appreciate it is difficult to draw a hard and fast line, but if we had a rule covering the majority of such cases it would prove a real help.

We know one large concern which takes the stand that when goods are accepted and receipted for by the railroad company, their responsibility ceases; when the packers' list is properly checked, they also refuse to make good any reported shortage; they positively will not ship a replace part without definite advice that the customer intends to pay for such replacement. In other words, they take the stand that they (the manufacturers) are right which is just the opposite to our policy.

However, we are beginning to question whether our policy is proper under present conditions. We all know that boilers are being sold today on a very close margin, and there is simply not enough room above actual cost to take care of unjust back charges.

Address communications to H. N. Covell, secretary, American Boiler Manufacturers' Association, 191 Dikeman Street, Brooklyn, N. Y.

## Horsepower of a Horse to Be Determined

THE actual horsepower of a horse will be determined at the Iowa State Fair this year where scientific tests will be made.

A specially constructed wagon has been designed for the tests by the engineering department of the Iowa State College. By means of gears and a hydraulic pump driven from the wheels, it will be possible to put on any predetermined load and maintain uniform load resistance from the test wagon, whether it travels on a level or up or down hill. The teams probably will be required to pull a six-horsepower load to enter, the load to be increased by two horsepower on each successive trial until the maximum is reached.

Horsepower has been a standard of power measurement for years, but little research work in the hauling power of horses and mules has been carried on scientifically because of the difficulty in providing a uniform tractive resistance.— *Power*.

## Results of a Recent Investigation of the Strength of Welded Pressure Vessels*

A N extensive publication has been prepared which may be divided into three parts, namely: A report of tests carried out by the Bureau of Standards; an analysis of test data given in this report and comments on the various features considered; and finally, recommendations made by the Pressure Vessel Committee of the American Bureau of Welding for the consideration of the Boiler Code Committee of The American Society of Mechanical Engineers in their revision of the Code for Unfired Pressure Vessels.

As regards the report of the Bureau of Standards, it deals with an investigation of the strength of welded pressure vessels. As it is expected that it will be published by the Bureau in the usual manner, at which time it will be available at a very low cost to all those interested in the subject, only the conclusions arrived at are reported here. These are:

1 The double V-weld is much superior to the single Vweld.

2 The pipe shells tested were less uniform and averaged lower in strength than double V-welded plate shells.

3 The butt-welded heads were stronger than the inserted heads.

4 A hammer test cannot be relied upon to show more than a very few exceptionally defective welds.

5 The hammer test, as applied, apparently did not weaken the tanks.

6 Hydrostatic pressure  $1\frac{1}{2}$  times the working pressure showed only a small number of imperfect welds, even when the hammer was used.

7 Hydrostatic pressure sufficient to stress the shell to the yield point will show a large proportion of imperfect welds.

8 Hydrostatic pressure sufficient to produce a permanent set in the shell, enlarging the circumference  $\frac{1}{2}$  percent, apparently does not weaken the tank.

9 Flanges for inspection plugs can be welded in the heads of a tank without weakening it.

The comments on the report of the Bureau of Standards fall into several sections. In those dealing with construction it is pointed out among other things that there is one principle which it is felt should be carried out in all welded steel structures of importance, which is that the included V-angle should not be less than 90 degrees.

The shells in these tanks were crimped over the heads, a construction that is thought by many to give added strength. There is some doubt, however, as to its effectiveness, though this must increase as the diameter of the tank decreases, the thickness of the shell and the amount of crimping being the same. The drawing of these tanks submitted by their maker shows such an amount of crimping as to make the V-angle so small that it is quite impossible to make the weld as indi-The photograph of the actual sections shows this cated. to be true, and it seems clear that, considering the small amount of weld metal actually holding, and the fact that there is bad bending action in the weld, the very high factor of safety is all that saves the construction from failure, and so the design cannot be commended. It is believed that other designs, more efficient, and probably just as cheap, are available, and that they should be used in the interests of safety. Of course there can be no objection to the use of pipe for the shell with a proper factor of safety, and with flanged heads butt-welded to the shell the construction would be beyond criticism.

In one of the tanks tested, in fact, the strongest of the lot,

it was found that there was a severe strain on the head weld caused by its rigidity which kept it from bending while the material on both sides of it could distort. In another instance one of the head welds cracked under the hammer test.

The maker reports that during the 50-lb. hydrostatic shop test for tightness there were found two damp spots, one in each head seam, which were rewelded, and after retest were found tight. It is not possible now to identify these spots, but the crack may be at one of them.

This rewelding might account for a local stress, which, added to the test stress, might be of sufficient amount to cause local rupture. It is a very good illustration of what may occur if enough care be not taken in making repairs.

There are three points to note in this connection:

1 The static test at 1¹/₂ times the working pressure did not detect the defect.

2 The defect was found by the hammer at a lower pressure than  $1\frac{1}{2}$  times the working pressure.

3 The crack was evidently caused by local internal stresses because (a) it occurred at low pressure and (b) it was local.

So far as this case is concerned, it seems clear that something more than a static test is needed, and that a shock of moderate amount while the tank is under moderate pressure will show up defects not revealed by a static pressure of the same or somewhat greater amount.

It is probably a good thing that this tank failed as it did, as it shows that the Code provision for a reweld and retest is safe practice if the work is properly done. It is also evident that local stresses can exist in otherwise properly welded tanks, and that they have no effect on the strength of the rest of the welds.

### DESIGN OF TANKS

It is claimed that the best method for applying heads is by butt-welding a flanged head to the shell, and where a head convex to the pressure is used the method in the Code should be followed.

As regards the question of what fiber stress should be used in designing unfired pressure vessels, the conclusion is reached that it seems quite fair and safe to use 50,000 pounds as the basis for design. With a factor of safety of 5, and a weld value of 80 percent, this would mean a design fiber stress at the working pressure of 8,000 pounds, based on the nominal plate thickness. In view of the high efficiency of the double V-weld, 97 percent or 9,700 pounds fiber stress, using the above basis, this does not seem to the committee excessive, unfair, or in any degree dangerous, and they therefore recommend its adoption. It would apply also to the special tanks, only 4 of the 23 having less than 50,000 pounds tensile strength.

For wrought-iron pipe used for pressure vessels a maximum working fiber stress of 4,000 pounds is recommended, although it is pointed out that steel pipe is just as easy to obtain and makes the construction safer.

The committee considers it inconsistent to allow 150 pounds for air tanks and 250 pounds for ammonia tanks. It believes that it is entirely safe to put all liquids or gases on the same basis as far as welding is concerned.

The committee also objects to the requirement in the Code to the effect that heads convex to the pressure shall have a skirt not less than 3 inches long. This is impractical for smaller-sized heads and the committee recommends certain relations between the length of the skirt and the diameter of the head. Also the committee believes that the constricting

*From Mechanical Engineering.

or crimping of the end of the shell is unnecessary, although not objectionable. The committee also recommends a certain form of convex head. The necessity for this is due to the fact that as heads convex to the pressure are much thicker than the shell, the welder is at some disadvantage unless the head is reduced in thickness. There are a number of other recommendations which cannot be reported here on account of lack of space.

### HYDROSTATIC HAMMER TEST

A search was made by one of the committee, but only a few references have been found, and they are merely references to the fact that it is used.

The American Society for Testing Materials provides in its specification for cast-iron pipe as follows:

SECTION 14. The straight pipes shall be subjected to a proof by hydro-static pressure, and if required by the engineer, they shall also be subjected to a hammer test under this pressure. [No details of how the test is to be applied are given.] The pressure to which the different sizes and classes of pipes shall be subjected are as follows:

-Test Pressure-

Class	Working Pres- sure ¹	20 in. Diam. and Larger	Less Than 20 in.	FiberStress at Test Pressure	Fiber Stress at Test Pressure ²
A	43 lb.	150 lb.	300 lb.	4 in., 1,420 lb.	20 in., 2,230 lb.
B C D	86 lb. 130 lb.	200 1b. 250 1b.	300 lb. 300 lb.	18 in., 4,200 lb.	60 in., 3,230 lb.
Ď	173 lb.	300 lb.	300 lb.	4 in., 1,150 lb 18 in., 2,760 lb.	20 in., 2,900 lb. 60 in., 3,780 lb.

¹Added to table. ²Calculated from data in specifications.

It will be seen that the ratio of test pressure to working pressure varies widely-from about 7.0 to 1.7-and that the fiber stresses in the table are likewise irregular and variable. The committee is not in a position to criticize, and simply points out the variations as indicative of either unusual conditions or of lack of standardization, probably the latter.

The data and wording of the American Water Works Association specifications are identical with those of the American Society for Testing Materials.

Statements are given of methods of hammer testing castiron and steel pipe. From both it will be seen that the hammer used is not heavy, and, from a study of the tables of test pressures, that the fiber stresses used are not as high as in the Bureau of Standards' tests. The test pressures in the proposed revision of the A.S.M.E. Rules for Piping and Fittings are the same as those of the American Society for Testing Materials, and no hammer test is specified in either case.

On the other hand, there are data in favor of this test. One of the members of the Boiler Code Committee, who is a strong advocate of the Code test, states that in his experience it has been of much value in detecting leaks and other imperfections.

One of the members of the present committee, who has used the hammer test for several years, states that by employing it some leaks have been found that were not shown up by the pressure alone, and he would not want to omit its use.

It has been the experience of one job welding shop, in the case of many hundreds of cast-iron vessels, ranging in size from small auto cylinders to very large heating-boiler sections, that, with a city water pressure of from 40 to 60 pounds, an ordinary machinist's hammer, used in proportion to the weight of the vessel, will invariably detect a strain due to uneven shrinkage, and that if no effect is produced by the hammering, there is also invariably successful service. It has also been their practice for over five years, in cases where the working pressure is known, to use the Code test on all welded cast-iron pressure vessels, such as steamjacketed kettles, and they state that they would not feel safe in letting them leave the shop without being so tested, and that no vessel of this type passing this test has ever failed in service.

It is their belief that the test is specially adapted to detect strains, which are serious in cast-iron welds, and that it will not, from their experience, detect an imperfect cast-iron weld unless there is a strain in it, because the factor of safety in the vessels, referred to is made very high because of foundry conditions, so that even an imperfect weld will be plenty strong enough.

The statement usually made as far as the committee knows, is that the Code test should detect a bad weld. At once the question may be asked, What is a bad weld? The committee knows of no attempt to evaluate or define it. There tre evidently various degrees of badness in welds, as in anything else, but in the tests no "bad" weld was detected by the Code test except one (Tank X15). The other one found by it was a good weld (Tank K4), containing a local strain, which was repaired and the tank on retest broke at 50,500 pounds fiber stress. It is quite probable that X15 had a strain in the weld, due to the thin welds having to stand all the shrinkage stress.

The committee has inquired of its members and others as to their idea of a bad weld, which would be discovered by the Code test, and has found that none of those questioned had any definite opinion on the matter.

The Code has no specifications for the pipe which was used for nine of the regular tanks tested. The committee feels that wrought-iron pipe being naturally weak longitudinally in the tank or transversely in the skelp, is not a suitable material for pressure vessels unless the factor of safety is very high, and that lap-welded steel pipe could be used instead without any hardship.

The subject of high- or low-tensile-strength plate for welding is discussed in some detail. As regards the yield point, it is believed to be perfectly safe to allow a high yield point, especially since the material is annealed by the welding for quite some distance from the weld. This annealing increases the elongation, allowing the steel to absorb the welding strains in spite of higher tensile strength than the Code allows. From the foregoing it is safe to provide that material 1/4 in. thick or less shall have the following physical properties:

provided that the elongation be measured on a gage length of 24 times the thickness and that the Code chemical analysis be complied with, and the committee so recommends. The committee believes that the use of a definite minimum for the yield point is not as good as the limit used in the Boiler Code in which the yield point is equal to 0.5 T.S. min., because the former excludes Armco iron, a very good material, while the latter admits it. Whatever form of specification is used, Armco iron should be allowed. Further, the committee believes that if its recommendation as to hydrostatic test at three times the working pressure be adopted, the yield point minimum of 24,000 pounds is too low, as it is just three times the fiber stress, 8,000 pounds, of which the committee is in favor.

## CHEMICAL REQUIREMENTS OF PLATE

The committee recommends the following as a specification that will fit all cases:

Percent Max.	Pe	rcent Max.
Carbon 0.15 Manganese 0.30 to 0.60	Phospherus Sulphur	. 0.01

It is believed that there should be a low limit on the manganese, to insure good steel, and 0.30 per cent is recommended. This would exclude Armco iron, which is entirely suitable for pressure vessels, provided its low tensile strength (about 45,000 lb.) is allowed for, and its use should be permitted by some such wording as, "The use of ingot iron is permitted provided a fiber stress of 7,200 lb. per sq. in. at the working pressure is not exceeded." (Journal of the American Welding Society, vol. 2, no. 5, May, 1923, pp. 11 to 162, 120 figs., epA).

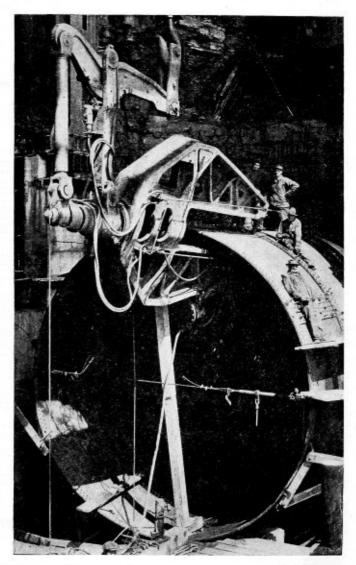

## Record of Riveting Made on Heavy Pipe Work

## Schedule of Forty-five Rivets in Thirty-five Minutes Maintained by Largest Portable Riveter in Use

A RECORD of 450 rivets in a working day of 8 hours has been the average performance of the bull riveter in use on the penstock work at the Niagara Falls Power Company tunnels at Niagara Falls, N. Y. On a regular run 45 rivets in 35 minutes was the schedule. The riveter, the largest portable machine in use, was built by the Hanna Engineering Co., Chicago.

Work on the second penstock has just been completed so far as the services of the riveter are concerned, and the third is not yet ready for riveting. The labor saving accomplished is computed at 66 per cent. The average work of a crew of seven men hand-riveting is 150 rivets in an 8-hour day. The labor-saving feature is enhanced, it is held, through the fact that with hand-driven rivets a percentage must be allowed for cutting out loosely driven rivets—a condition not found in the machine-driven work.

The rivets used on the penstocks are  $1\frac{3}{8}$  and  $1\frac{1}{2}$  inches in size. The plates are  $1\frac{3}{8}$  and  $1\frac{9}{16}$  inches in thickness,

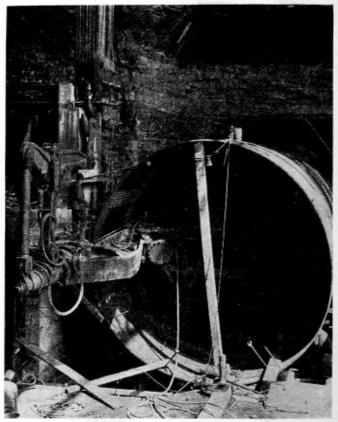

Riveter at Work on Penstock

and were rolled at Homestead. The jaws of the riveter compress the plates under pressure of 150 pounds.

## CAPACITY OF MACHINE

Each of the three penstocks is 21 feet in diameter for the supply of 70,000 horsepower turbines. The Hanna machine

The Riveter is Readily Controlled in Any Position

weighs 20 tons, and is slung from an overhead crane. It is balanced so that the operators can swing it in any position desired with but little effort. Air operated worms raise, lower or turn it.

The work on the penstocks is done in the open, and as each ring is completed the tube is rolled into place on rails.

## New Record in Repairing Locomotives

THE railroads of the United States from July 15 to August 1 repaired and turned out of their shops the largest number of locomotives for any semi-monthly period in their history.

Of the total number on August 1, 10,370 or 16.2 percent of the number on line were in need of heavy repair, a decrease of 414 since July 15. There were also on August 1 this year, 1,185 or 1.9 percent in need of light repair, an increase, however, of 114 over the number in need of such repair on July 15.

## SEPTEMBER, 1923

## for Government Dredge

NOTICE has been sent out from the U.S. Engineer Office at Montgomery, Ala., that proposals will be re-ceived until 11 A. M., October 1, for furnishing one steam boiler, with fixtures, stacks, etc., for U. S. dredge Upatoi, at Columbus, Ga.

## DETAILED SPECIFICATIONS OF BOILER

Work to be done: The work to be done under these specifications is to furnish and deliver at Columbus, Ga., one Scotch Marine water-back boiler with equipment as listed below:

The following specifications are intended to describe in a general way the type and size of the boiler only. Bidder shall make all necessary computations for the thickness of plate, riveting, staying, etc., to obtain the working pressure stipulated.

General description. The boilers shall be built to comply with the General Rules and Regulations prescribed by the Board of Supervising Inspectors, Steamboat-Inspection Service (rivers), latest edition, in regard to design, construction, material, and workmanship for a working pressure of 200 pounds per square inch.

Cuts and description. Bidders shall submit cuts, blue prints, and a full description, with dimensions and weights, of the boilers they propose to furnish.

Tracings. As soon as practicable after receiving notice of award of contract, the contractor shall prepare and submit to the contracting officer for approval, two sets of detail tracings showing plan, cross section, and front and rear elevations of the boiler, with fittings attached. These sets of drawings shall become the property of the United States.

Boiler. One Scotch Marine Water-back boiler designed for a working pressure of 200 pounds per square inch. The shells shall be made of open-hearth steel having a tensile

Estimate Being Asked for Scotch Boiler strength of 60,000 pounds per square inch; boiler to have not less than 1,200 square feet of effective heating surface and not less than 37 square feet of grate area. Furnace shall be of the Morrison suspension type and removable without removing front or back flue sheets. Tubes to be of genuine knobbled charcoal iron one gage heavier than standard. Boiler to be fitted with cylindrical steam drum of proper size with 5-inch main steam connection on side of drum facing toward end of boiler opposite the firebox. Boiler to be fitted with three 3-inch auxiliary steam connections along top of boiler spaced along center line. Suitable connections to be provided for 2 feed water lines, gage cocks, water columns, safety valve and blow-off valve, etc. Manholes and handholds of proper sizes shall be fitted in head of boiler, steam drum, top and bottom of shell, and provided with cast steel covers and yokes, and with necessary gaskets and bolts.

Feed water connections. Two feed water connections shall be placed in front head of boiler at sides above the top row of tubes and same shall be provided with brass bushings and internal feed pipes extending from the front end of the boiler to within about 3 feet of the rear tube sheet, thence downward near side of shell for discharge near bottom of boiler.

Supports. There shall be furnished with boiler for supports three cast iron saddles of proper design, distance from deck plate to bottom of boiler to be 9 inches at center line.

Limiting dimensions. Length of boiler shell shall not exceed 18 feet; height from top of steam dome to bottom of saddle not more than 11 feet.

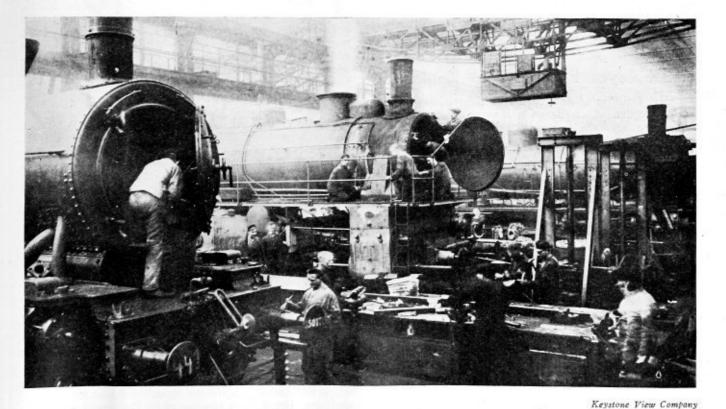

Fittings. Boiler shall be furnished with the following fittings:

Boiler front with liners and doors suitable for use with shaker grates as specified.

Steel breeching and uptake, height of smokestack connection (top of breeching), to be not more than 11 feet from deck.

One brass rim steam gage-12-inch diameter.

One safety water column with high and low water alarm.

A View of the Interior of the Famous Krupp Locomotive Works at Essen, Germany, in the Ruhr District

fitted with extra heavy bronze mountings for glass water gage of an approved type.

Three try cocks.

One stop valve for main steam connection.

One combination stop and check valve for main feed connection.

The combination stop and check valve for auxiliary feed connection.

One bottom blow-off valve of an approved type.

Bridge wall of an approved type.

One complete set of shaking and dumping grates of an approved type for burning bituminous coal.

One marine spring safety valve.

### STACKS AND BREECHING

Stack. There shall be furnished with the boiler one stack of suitable diameter, 36 feet in length built of 14-gage steel and furnished in two sections, the upper section hinged 10 feet above the breeching with stack hinge of approved design. Four angle lugs and stack band for attaching guy wires shall be riveted on stack near the top of each section. An outside casing of 16-gage sheet, 3 feet long and 16 inches larger in diameter than the stack shall be furnished. Top of this casing will be supplied with a storm hood made in 2 sections, to bolt tight around stack and extend beyond outer casing. Four angle iron supports of proper size shall be bolted to the outer casing at a point one foot from bottom end to suspend it in roof of boiler room. Stack and casing shall be given 2 coats of black heat-resisting paint. *Inspection.* The boilers will be subject to inspection by

Inspection. The boilers will be subject to inspection by local inspectors of the United States Steamboat-Inspection Service and also by the contracting officer or his authorized representative. The contractor shall give these inspectors access to all parts of the work and such facilities as may be required for the proper performance of their duties.

Tests. Before shipment the boilers shall be hydrostatically tested by the contractor to a pressure of 300 pounds per square inch, in the presence and to the satisfaction of the local inspector of boilers, United States Steamboat-Inspection Service, or by representative of the contracting officer. The contractor shall make good to the satisfaction of the contracting officer any defects that may develop during the test.

## Employee Education in England

THE facilities offered by the British railways for the education of employees are noteworthy, particularly since they have not restricted their efforts in this direction to the training of apprentices in the mechanical department, but have extended them to practically all departments. Before the amalgamation of all the railways into four regional groups, which took place on January 1, each company had its own plan. Naturally certain modifications were to be expected as the result of the consolidation and one of the first of these to be announced is the extension of the educational facilities offered to railway clerks of the Great Northern Railway to employees of that class of the entire London & North Eastern group. The courses of instruction are, in every case, conducted by local colleges and universities at various important railway points. The educational institutions provide the instructors and arrange the details of the work to be covered. The railway pays the greater part of the tuition and arranges for the furnishing of text books at reduced prices. For the forthcoming school term instruction will be offered in four subjects, viz., railway operation, the law relating to the conveyance of freight and passengers, railway and commercial geography and railway economics. Arrangements have so far been made for courses at eleven points along the company's lines. Each course consists of 20 lectures of one hour each and prizes are awarded by the

company varying from \$5 to \$25, according to the standing of the student, for all who successfully pass the examinations given at the conclusion of each course. The continuance of these courses and their extension to all the railways of the group indicate that they have been successful in giving the employees a broad knowledge of railway work and in fitting them for promotion.—*Railway Age*.

## Iron and Steel Exposition to be Held this Month

JOHN F. KELLY, national secretary of the Association of Iron and Steel Electrical Engineers, has extended to the readers of THE BOILER MAKER a special invitation to attend the Iron and Steel Exposition, being held at the Broadway Auditorium, Buffalo, New York, September 24 to 28, 1923.

Over one million dollars' worth of apparatus will be on display and will represent what 150 of the largest manufacturers in the United States have developed for the use of the industries during the past year.

A special feature will be the complete electrified foundry which will be in actual operation producing finished castings. Starting with the electric furnace, every operation known in modern foundry practice will be exemplified and as this is the first time that this feat has been attempted in America, it will attract thousands of foundrymen from all over the United States.

The technical sessions which are held in connection with the Iron and Steel Exposition have all been prepared with a view of imparting the practical experiences and data obtained by the engineers in the field of operation.

## National Safety Council

"HE National Safety Council will hold its twelfth annual Congress at the Hotel Statler, Buffalo, N. Y., on October 1, 2, 3, 4 and 5. The opening session is on Monday morning at 10 o'clock, when Marcus A. Dow, president of the council, will deliver his address. Another address on Monday will be that of H. A. Rowe, claims attorney of the D. L. & W., in the afternoon, on the careful crossing campaign. On Tuesday afternoon, there will be an exhibition of 100 new safety stereopticon slides, showing new developments in safeguarding. These will be presented by C. B. Auel. Another item of interest to railroad men will be a discussion, on Wednesday evening, of the bulletin board as an indispensable safety advertiser. Mr. Dow is scheduled to speak again on Tuesday afternoon, before the public safety session, on the work which he has been doing in the Bureau of Public Safety of the New York Police Department.

The foregoing are the principal items in the program which appear to be of special interest to readers of the THE BOILER MAKER, until we come to the steam railroad section. This section, of which L. G. Bentley, of the Chesapeake & Ohio, is chairman, is to hold sessions in the forenoon of Tuesday, Wednesday and Thursday. A dozen interesting topics are scheduled for discussion at these sessions but the speakers have not yet been announced.

## W. E. Smith Selected by Boiler Code Committee

The A. S. M. E. Boiler Code Committee has recently appointed W. E. Smith, chief boiler inspector of the Boiler Inspection Department of the Hawaiian Sugar Planters Association, Honolulu, a member of its Conference Committee representing the Hawaiian Islands.

Early in the present year the American Railway Association outlined a definite plan for the railroads to follow in meeting the demands for motive power which seemed certain to arise during the summer and fall months. One of the resolutions adopted by the association provided that by October 1 locomotives requiring heavy repairs be reduced to a basis for the entire country of 15 percent.

At that time the number of locomotives in line for heavy repairs was about 21 percent with the majority of shops just beginning to recover from the strikes of the previous year. The prospect, therefore, for the realization of what would constitute a record for locomotive maintenance seemed rather hopeless.

With the approach of the fall season, however, the possibility of accomplishing the desired reduction in bad-order locomotives seems better. Available records indicate that from July 15 to August 1 the railroads of the United States repaired and turned out of their shops the greatest number of locomotives for any semi-monthly period in their history. During this period 22,200 locomotives were repaired exceeding by 794 the record previously made during the last two weeks in May of this year. The locomotives in need of repair on August 1 totaled 11,555 or 18.1 percent of the total number on the line. This was a decrease of 300 as compared with the number on July 15 when there were approximately 18.6 percent.

On August 1 the heavy repairs were reduced to 16.2 percent which indicates that as far as the boiler departments are concerned the record of 15 percent by October 1 will undoubtedly be realized. This fact is particularly interesting because of the necessity in many cases of training entirely new men for carrying on the shop work.

In meeting the heavy locomotive demand of the past few months many of the railroads have found their capacity inadequate for maintaining the repair schedules laid out for them. As a result, locomotives in increasingly greater numbers have been sent to contract repair shops which have been built up with the idea of accommodating the peak requirements of several roads in a given territory.

A description of a contract plant, with details of its development from a war-time ordnance plant, appears in another section of this issue. The location and arrangement of the shops, as well as the equipment, were readily adapted to locomotive repair work on an extensive scale. In fact in one respect this plant is superior to practically every locomotive shop in the country—that is in its crane equipment which is made up of many special type ordnance cranes, the cost of which for the usual repair shop would be prohibitive. With this equipment, however, the work is put through the shops with great dispatch.

The greatest difficulty in establishing the plant occurred in creating a skilled organization capable of maintaining the standards of the roads for whom repairs were contracted. To a large extent men engaged in the repair work are semiskilled rather than fully qualified mechanics. For this reason the work has been specialized in all departments under the direction of the superintendent of the locomotive repair department. About 80 percent of the men in the boiler shop for example were employed in various other capacities than boiler makers previous to their engagement with the company. Each man, however, has been taught to perform the operations assigned to him with great skill so that the specialization of the individual has more than compensated for the lack of all around boiler makers.

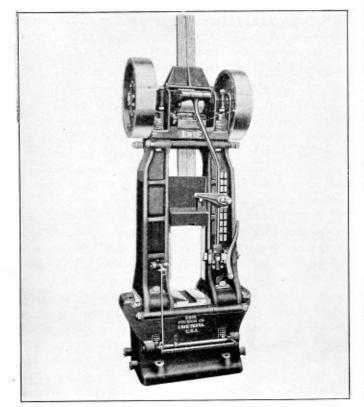

The showing made by the plant during the month of July of 40 heavy repairs is a creditable one and the system of contract shops such as this when operated efficiently offers a degree of relief to the railroads by providing facilities during peak periods when their own shops cannot accommodate all of their motive power without a great over expansion for the dull periods.

## Engineering Specialties for Boiler Making

New Tools, Machinery, Appliances and Supplies for the Boiler Shop and Improved Fittings for Boilers

## **High Production Board Drop Hammers**

THE Erie Foundry Company, Erie, Pa., has brought out a new line of board drop hammers, characterized by a refinement of detail rather than by any radical departure from accepted principles of construction. Many ideas

Erie Board Drop Hammer, Made in Sizes from 200 pounds to 4,000 pounds, inclusive

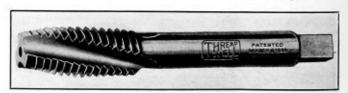

developed by actual forge shop experience and now considered as standard in heavy steam drop hammer construction have been adapted to the new line of board drop hammers. A thorough study has been made of the troubles experienced with existing types and practical drop forgers consulted as to the best methods of correcting these faults, the idea of the builders being to achieve a machine capable of a high-rate of production at a minimum of operation and maintenance expense, and dependable even under the severe conditions to which drop hammers are subjected.

Among the outstanding features of the new hammers are wedge adjustment of the frames across the anvil, the use of tie bolts and separators between the frames at the bottom and a new type of latch. The wedges hold the frames and anvil together as a solid unit, making it easy to maintain the alinement of dies and at the same time making adjustment easier. The new type Erie hammer has a greatly increased tongue and groove area; also several details of the operating mechanism have been improved. The point of knock-off is easily adjusted, assuring that adjustment will be made as often as desirable and that the rolls will grip the board at just the proper moment. The friction bar drops vertically in guides, the latch bar being moved by the descending ram from under a block which fits against a shoulder on the bar. As the ram ascends, a hickory pin strikes one end of the roll release lever which is pivoted on a block clamped to the friction bar. Thus the friction bar is lifted gradually and without shock. The other end of the roll release lever bears on a pin which is adjustable up and down on a rack cast on the frame by means of which the length of strokes is varied. The crosshead construction used at this point reduces wear and shock.

The ram is an open-hearth steel casting, cast by a special process to assure a dense structure of clean metal. The main bearings are bushed with phosphor bronze, and ample bearing area is provided. The anvils can be furnished in the ratio of 15 to 1 or of 20 to 1 to the weight of ram. The pulleys can be of wood, paper, or steel, to suit individual requirements. The new line of Erie hammers is built in sizes from 200 lb. to 4,000 lb. weight of falling parts.

## Spiral-Fluted Tap

A LINE of "Threadwell" right-hand spiral-fluted taps in which the thread is ground, is manufactured by the Wells Corporation, Greenfield, Mass., in nine screw-gage numbers from 2 to 14, inclusive, and ten fractional sizes from ¼ to 1 inch, inclusive. Each cutting edge has three points of clearance, due to the rake angle of the spiral, the rake angle of the hook in the flutes, and the clearance of the eccentric relief. The tap is said to be designed on the same principle as a properly ground lathe tool, and these clearances are similar in effect to the back rake, side rake, and under-cut clearance of a lathe tool. The

Wells "Threadwell" Spiral-fluted Tap

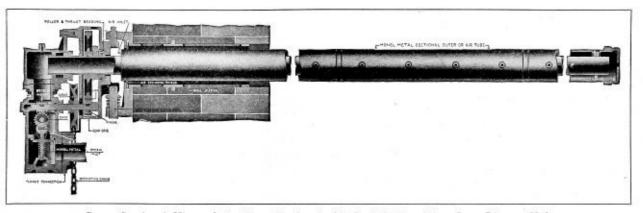

right-hand spiral flutes curl the chips and convey them out of the hole.

The tap is regularly made with a short "plug" chamfer for tapping all holes except blind holes where a full thread is necessary clear to the bottom. In such cases a very short chamfer is ground on the tapping end. In addition to the eccentric relief, an extra chamfer is given at the point where the taper and straight portions of the tap would otherwise meet. It is said that this double taper results in a more even distribution of the cutting strains and makes the tap less liable to breakage; in addition, less power is required for operating. The edges of the starting or chamfered threads are rounded, and all sharp corners removed to narrow the teeth and enable them to catch a thread without a reaming effect. Accuracy, both in diameter and lead, is guaranteed within 0.0005 inch.

## Air Cooled Revolving Soot Blower

O^{NE} of the latest developments in mechanical soot blowers has just been introduced by the Bayer Co., 4067 Park avenue, St. Louis, Mo. This device is sectional and, being made from monel metal, or charcoal iron as conditions require, is claimed to be non-warpable. Cooling is accomplished by air. The revolving soot blower unit is regularly furnished equipped with a geared head without valve. The geared head is completely encased, no parts being exposed to dust or grit. As the head is full floating it has freedom of movement in any direction. A re-

it, however, are furnished a 350-pound anvil with a coneshaped horn for belling the ends of the flues preparatory to receiving the safe ends, and a ball and roller bearing stand to support the outer ends of the tubes while in the welding machine. After the tube has been prepared to receive the safe end and heated with the safe end in place, the weld is made on the machine by slipping the heated flue and safe end over the lower mandrel or inside roller and bringing the weld under the upper or outside roller. A stop can be provided on the mandrel by placing a short piece of flue of the proper length on the back of the arbor. With the rollers in motion, the upper roller is brought down in contact with the flue by means of an air cylinder operated by the foot lever shown in the illustration. This lever is first pressed lightly while the flue makes two or three revolutions. The pressure is then increased, causing the two rounding rolls shown in the illustration below the inside mandrel, to move up against the flue. Care must then be taken not to continue the rolling too

Cross Sectional View of the New Sectional, Air-Cooled, Revolving Soot Blower Unit

duction gear makes it impossible to revolve the unit too rapidly.

In the accompanying illustration is shown a cross-sectional view of the blower equipped with the valve. The outer sectional air tube is joined together by means of expansion sleeves which allow for expansion and contraction. The monel metal nozzles are secured to the interior steam element, expansion space being left around each nozzle where it comes through the outer or sectional air tube. Discharge or blowing of the steam jets is mechanically timed and the jets are blown within a predetermined arc. Rotation is possible in either direction, the movement being controlled by a light chain and a sheave wheel mounted on the head.

One of the features claimed for the blower is the accessibility to the valve and other operating parts. The valve mechanism is reached through a cap at the bottom of the blower head without the necessity for breaking any steam connections. Steam connections can be made in a horizontal position or any other way desired for convenience or to save piping.

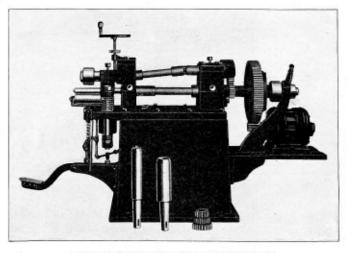

## Roller Type Flue Welder

HAT is known as the Marshalltown-Schaefer flue welder has recently been developed by the Marshalltown Manufacturing Company, Marshalltown, Iowa. A distinctive feature of this welder is the use of two revolving rolls, one inside and one outside of the flue, between which the weld is made. These two rolls are power driven at a comparatively slow speed and are connected by gears, the ratio of which causes both rolls to operate at the same circumferential speed.

The illustration shows the welding machine alone. With

long or the size of the flue may be enlarged. With the roller bearing adjusted so that it is in line with the inside mandrel, the revolving of the flue while the weld is being made alines the flue and the safe end so that when the weld is complete the whole piece is straight.

The machine has a welding range which will take tubes from 2 to 6 inches in diameter by changing the rolls, and

The Marshalltown-Schaefer Flue Welder

pieces up to 9 inches in length can be welded on the flue. Three sets of rolls are furnished with each machine and a small hand wheel adjustment is provided at the top so that the welding roll may be correctly set about 1 inch above the mandrel in each case.

## Questions and Answers for Boiler Makers

Information for Those Who Design, Construct, Erect, Inspect and Repair Boilers—Practical Boiler Shop Problems

Conducted by C. B. Lindstrom

This department is open to subscribers of THE BOILER MAKER for the purpose of helping those who desire assistance on practical boiler shop problems. All questions should be definitely stated and clearly written in ink, or typewritten, on one side of the paper, and sketches furnished if necessary. Inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

## **Transition Piece Intersecting a Cylinder**

Q.-Inclosed please find clipping from a drawing which I have had no small amount of trouble trying to develop. You will note the sections I refer to are marked "1" and "1-A."-I H. S.

A.—In the development of intersections of this character it is necessary to develop three views of the connecting object, as indicated in Fig. 1. The plan and side view will appear the most difficult since there are two steps in the development for obtaining the miter line. These will be understood from the explanation.

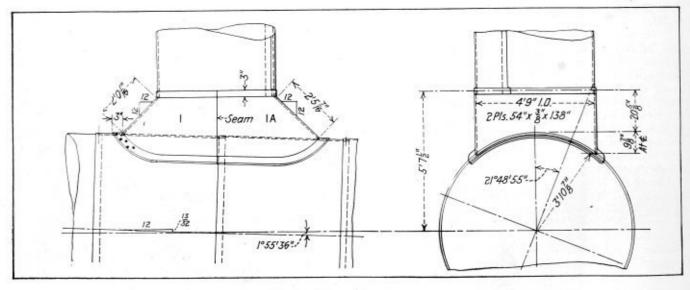

The outline of the transition piece and the cylinder in the end and side views are drawn first, then the circle in the plan The points u, v, w and y are located on the plane x-x of the elevation. Lines are then drawn connecting points 2-y, 3-w, 5-v and 6-u as indicated in the elevation for the parts A and B. From the end view projectors are extended to the side view intersecting the radial lines as shown in the points 2, 3, 5 and 6 which lie on the miter line.

The points located on the miter are then projected to the plan view to locate their relative position as indicated at  $I', Z', J', f', S', \delta'$  and T'. The solid line through these points represents the line of intersection in the plan.

In the elevation, dotted diagonals are shown for which their true lengths must be found as shown in Fig. 2. Use the heights a, b, c of the elevation, Fig. 1, transferring them as shown in Fig. 2. The bases of the respective triangles are taken from the plan using the dotted lengths *I-2*, *2-3*, *3-4*, *4-5*, etc.

The solid lines *I*-*I*, 2-2, 3-3, 4-4, etc., of the elevation are shown in their true lengths in this view, as their corresponding projections in the plan are parallel with the horizontal axis  $I'-\overline{I}'$  or in other words parallel with front plane.

Before the patterns for A and B can be laid off, it is necessary to obtain the true arc lengths on the miter line. This may be done by developing first the shape of the opening

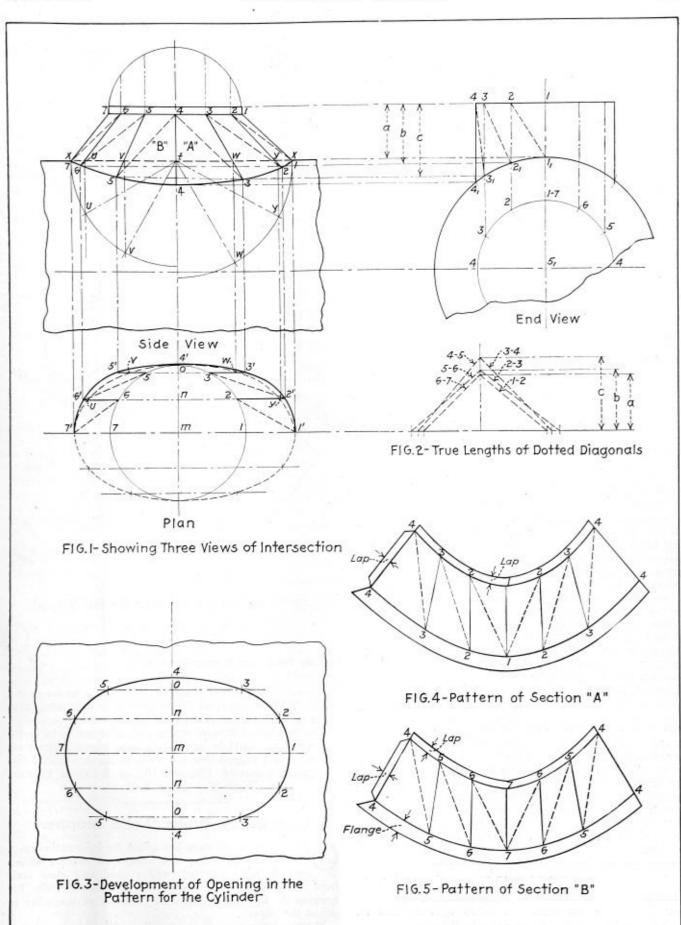

which represents the upper base of the object. The next step is to produce the shape of section as taken on the plane x-x of the elevation as follows: Divide the circle plan view into the desired number of divisions as from 1 to 7; likewise with the semi-circle drawn from point s of the end view. With t-1 and t-7 of the elevation as radii draw the quadrants shown. Divide each of these areas into three equal parts, locating points u, v, w, y which are projected to intersect the lines drawn through the points m, n and o of the plan. The dotted outline is the shape of the section on x-x.

where the transition piece intersects the cylinder as represented in Fig. 3. In this view, lay off on the line 4-4 the arc lengths I'-2', 2'-3' and 3'-4' of the end view, thus locating the points m, n and o through which draw straight lines at right angles to line 4-4. Transfer from the plan, Fig. 1, m-I', n-2', and o-3, and locate these lengths in Fig. 3, likewise, transfer the lengths m-7', n-6' and o-5' from the plan, Fig. 1 to Fig. 3, which gives the location of the points I, 2, 3, 4, etc. The outline of the opening is then drawn in.

The pattern for section A is given in Fig. 4 and for B in

## THE BOILER MAKER

SEPTEMBER, 1923

Fig. 5. The layout work for these consists of transferring the solid lines of the transition piece, Fig. 1, the dotted lines, Fig. 2 and using the arc length of the upper base as indicated in the end view, Fig. 1, together with the arc lengths of the opening outline shown in Fig. 3. Make the necessary allowances for lap.

## Elbow and Tapering Problem

Q.-Flease explain and show by development how the connections and patterns are made for the elbow sections shown in the accompanying sketch -W. T.

A.—The elbow pattern is obtained by first laying off an elevation of the elbow sections. Divide the arc *o-p* into one less than the number of required

less than the number of required sections, as o-e, e-f and f-p. Bisect arcs o-e and f-p as shown at g and h, respectively. Bisect the arc g-h at i, thus locating points for drawing radial lines to E. On these radials the miter between the elbow sections are located. Lines 4-4 are drawn tanent to the arc o-p. With e as a center, a circle is drawn equal to the diameter of the elbow. It is divided into a number of equal parts. Lines parallel to center line 4-4 are drawn from the points 1-2-3-4, etc., of the circle so as to intersect the miter lines.

A one-half pattern is developed on line m-n, from point f-6 equal divisions are set off equal to the arc lengths between points 1-2-3-4, etc., of the profile. Projectors are drawn at right angles to m-n and the points 1-2-3-4-5-6-7 projected to the pattern, parallel with m-nlocating 1'-2'-3'-4', etc. The other half is the same as the one shown developed. Patterns for the end sections A and D equal one half of the sections for B or C. Make the seams so that they are staggered with respect to each other.

The tapering connection cannot be laid off as frustums of cones. It appears from the original drawing that the bottom part of the branches are of a semi-cylindrical

shape and that the upper part was intended for a section of a cone. Making the upper part that way, you will note that it would not intersect the center piece properly and as will be seen from the partially developed plan. Note the reference letters in comparing the two views, the one-half ellipse is a development of the base of the one-half cone. The elements of the cone section do not touch the surface of the center frustum. In order to make the development the base connections of the branches will have to be modified to suit the conditions or the cone sections must be made smaller. If they are modified as shown to the right of the elbow triangulation must be used in laying off the miter line and pattern.

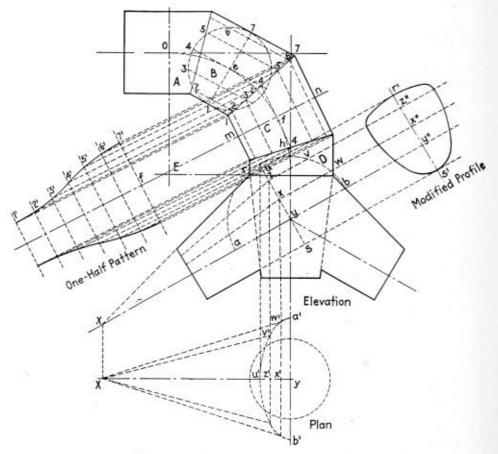

## PERSONAL

R. C. Young has retired as boiler shop foreman on the Chicago & Northwestern, at Baraboo, Wis., and is placed on the pension list, after being with the company almost 40 years.

## Flanging Blocks

Q.—Can you advise me as to how much flare to allow on flanging block to flange a straight head 14 feet 6 inches diameter: 5-inch metal with  $8\frac{1}{2}$  inch flange, same to be at right angle to face of head, and, as we are considering installing a gas burning furnace, will you kindly give any information you have concerning same.—W. G. K.

A.—Your inquiry on the flare is not quite clear. In flanging with formers under hydraulic pressure the plate follows the shape of the male former, therefore for all such work the face of the flanging die or blocks is made at right angles to the plane of the plate. In cold bending light sheet steel, some flare allowance for the male die is made to take care of the spring in the plate. In hot bending the flare is

Layout and Pattern for Blower Connection

not necessary as the hot bend makes a permanent set in the bend. Where contraction affects the flange in cooling it is set in or out by hand as required.

The problem of furnace design and construction for heating the plate should be handled by experienced contractors, and we would suggest that you write to the American Shop Equipment Company, Chicago; Ill., or Rockwell Furnace Company, 50 Church Street, New York.

## **Emergency Boiler Tube Stopper**

O^{NE} of our subscribers has asked for information on a self-acting emergency tube stopper for firetube boilers which, when inserted, will expand and close both front and back ends of the tube without the necessity for drawing the fire and going to the back end of the boiler to adjust the stopper.

If any of our readers are familiar with a device of this particular kind and where it may be obtained, we will appreciate his kindness in forwarding the information to us.

## Letters from Practical Boiler Makers

This Department Is Open to All Readers of the Magazine —All Letters Published Are Paid for at Regular Rates

## Testimonial Letters on Fuel Saving

W E are so accustomed to reading testimonial letters on fuel or money saving by the use of more modern equipment that such letters lose their intended effect. We are inclined very often, to doubt their veracity, especially when large savings are claimed. It is always so easy to exaggerate. Nevertheless, it is a fact that considerable fuel and money are commonly saved by replacing old equipment with something more modern and more efficient. It is becoming a very difficult task to convince owners of central stations, heating plants and industrial plants in general that this is true.

To assist the manufacturer of modern equipment in proving his claims and to stimulate more confidence on the part of the owners and officials of fuel buying and consuming plants I quote this from a small weekly newspaper, the Brookings, South Dakota, *Register*:

"Before the new boilers were installed the plant consumed about 260 tons of coal a month. Since the new boilers have been installed the consumption has been around 200 tons a month, a saving amounting to about \$700 a month ever since the new equipment was put in operation."

These boilers are installed in the municipal power plant belonging to the citizens of the city of Brookings. The figures are absolutely true.

And to make it still more interesting the writer knows that the power plant is now doing considerable MORE work as current is being furnished to a neighboring village, Volga, South Dakota.

Newark, N. J.

N. G. NEAR.

## Saw Mill Boiler Explosion Fatal

O^N Thursday morning, April 5, at ten A. M. a boiler exploded in a saw mill four miles east of Huntingburg, Ind., instantly killing Mr. Frank Pfaffs, owner, and injuring his son, Hubert, and Joe Mattingly who were working in the mill at the time tightening a pulley. The mill had just been shut down a few minutes before the accident on account of the loose pulley.

The son, Hubert, gave the following version of the acci-

dent: The boiler had recently been subject to a hydrostatic test of 165 pounds and found tight, but after the test was made the mechanic suggested that the safety valve be set to blow at 135 pounds. This they decided to do, but apparently their steam gage was not correct as the safety valve opened at 140 pounds by test after the accident. About the time the mill stopped the father went in the mill to assist the man in repairing the loose pulley, but the son noticed a small leak on the bottom of the boiler, calling this to the attention of his father, who went to investigate; just about the time he got to the back end, the boiler exploded.

On examination I checked the following: Length of boiler, 10 feet 6 inches; diameter of boiler, 34 inches; thickness of plates,  $\frac{1}{4}$  inch, all but tube sheets which are 5/16 inch; pitch of rivets,  $\frac{2}{4}$  inches; diameter of holes, 11/16 inch; diameter of staybolts,  $\frac{3}{4}$  inch; pitch of staybolts, 5 inches by 5 inches; diameter of dome, 16 inches; thickness of dome,  $\frac{1}{4}$  inch, single riveted; head, cast iron; all plates of steel, 60,000 pounds tensile strength. The boiler was 12 years old and had been worked continuously at 150 pounds until recently. The tubes were 5 feet 6 inches long and 2 inches diameter, the safety valve was  $1\frac{1}{4}$  inches diameter.

By referring to the illustrations the results are apparent. The cause was evidently grooving of the plate along the calking edge inside about 36 inches long and 3/16 inch deep (see small photograph of pieces cut out of ends). The boiler moved back about 12 feet; the firebox turned over; apparently the cylinder made a double turn, as a close study will show that the seam was on the bottom. The seam opened the entire length, tearing through the throat sheet and down a few inches, then straight across, then up around, about 2 inches back of the girth seam, apparently meeting near the center on the top. The wagon top sheet was ripped towards the back end about 6 inches. The front tube sheet and cylinder did not separate completely as ten rivets on the top were intact. All the other rivets were pulled through the holes. Note the bearing castings, those were on the top back of the dome. It is evident that this plate straightened out and then curled as shown.

The boiler evidently was thrown almost straight up in the air as the face of the man killed was mashed in and he was

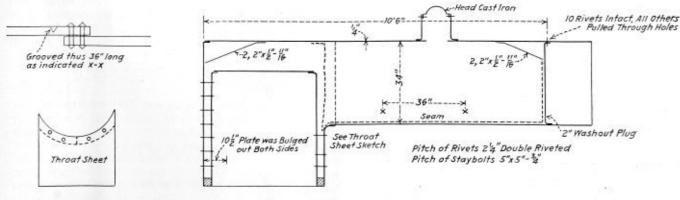

Fig. 1.-Diagrammatic Details of Boiler and Line of Failure

Fig. 2.-Scene of the Wreck. Grooving Along Calking Edge of Plate Responsible for Failure. (See Insert)

found in the open space in front of the wreck. A thorough hammer test in connection with the hydrostatic test might possibly have revealed the weakness as the metal was not over 1/16 inch thick at the bottom of the groove. Evansville, Ind. INSPECTOR.

## **Explosion** of Vertical Boiler

U^{NDER} the foregoing caption your correspondent, Mr. J. P. Morrison, of Chicago, Illinois, reports an explosion of a vertical tubular boiler (page 213 of the July issue of THE BOILER MAKER) and gives certain figures relating to the part of the boiler that failed, viz., the furnace sheet which was supported by 3/4-inch diameter staybolts pitched 8 inches by 8 inches apart.

It is not the writer's intent to criticize Mr. Morrison's letter except to say that your readers in general would probably be glad of more information regarding the details of construction and incidentally to comment a little on the action which produces the erosion or wasting away of the outer sheet adjacent to staybolts.

Concerning the shell construction, Mr. Morrison is silent so one can only make calculations from assumptions, but these seem to point to excessive pressure. Thus, with  $\frac{1}{4}$ inch shell, 55,000 pounds tensile strength, diameter 44 inches, and assuming the maximum efficiency possible, 77 percent, for double riveted lap joint with 11/16-inch holes on 3-inch pitch, we have—

Bursting Pressure = 
$$\frac{0.25 \times 55,000 \times 0.77}{22} = 481$$

pounds.

If a factor of safety of 5 be used, the safe working pressure would be only 96 pounds. In other words, the boiler was operating at more than 30 percent excess pressure, and by dividing the bursting pressure by the pressure carried, we

have  $\frac{1}{125}$  = a factor of safety of 3.84, on the highest pos-

sible joint efficiency. As a matter of fact such a joint is by no means common on account of the difficulty in calking a 3-inch pitch. Consequently it is probable the actual factor of safety in this case was much nearer 3 than 4. It is providential, in view of the proximity of persons at the time of the explosion, that the failure did occur in the firebox, thus expending the pent up forces downward instead of outward as would have happened if the outer shell had ruptured.

It is noted that Mr. Morrison attributes the deterioration of the sheet adjacent to the staybolt to feed water action, but the writer has frequently noted and believes that it is more. likely caused by the constant bending action on the staybolts produced by the greater expansion of the furnace sheet and tubes since these are subjected to higher temperatures than is the outer shell plate.

True, this action is most often found at the junction of staybolt and outer shell, and is doubtless assisted by some feed waters, but where the fire action on staybolt heads, coupled with expansion, has caused slight leaks to occur, the staybolt hold on the fire sheet is soon weakened, thus leaving the furnace to carry almost the entire collapsing load.

Using the Code as a guide, and disregarding the 5/16 inch minimum thickness required, this furnace had a right to be figured without staybolts, since it can hardly have been over 38 inches diameter. Once more resorting to assumption and judging from Fig. 1 (page 213, July issue), which shows 2 rows of staybolts, the furnace was probably about 25 inches in length.

The Code formula for such a furnace would give:

$$\frac{51.5}{D} \left\{ (18.75 \times t) - (1.03 \times L) \right\}$$
$$\frac{51.5}{38} (75.00 - 25.75)$$

$$1.355 \times 49.25 = 66.7$$
 pounds.

If now one adds the 34 pounds safe working pressure on

the staybolts to the safe working pressure on the furnace, it will be seen that a pressure of 100 pounds is obtained and that theoretically at any rate, the outer shell was probably the weakest part of the boiler.

Whenever possible, the writer prefers to go a step further than Mr. Morrison recommends and urges boiler users to invariably call in a recognized inspector whenever any boiler is to be retubed or major repairs are to be undertaken because it usually affords an opportunity to view surfaces that are otherwise inaccessible.

Numerous instances have occurred in the writer's experience where it has been conclusively shown that the expense of retubing or repairs was unwarranted by the conditions revealed.

San Francisco, Cal.

R. L. HEMINGWAY, Chief Boiler Inspector, California Industrial Accident Commission.

## Mr. Morrison's Reply

TO THE EDITOR, THE BOILER MAKER:

APPRECIATE the privilege afforded by the kindness of THE BOILER MAKER and our friend, Mr. R. L. Hemingway, of reviewing his comments on the article referring to the explosion of the Vertical Tubular Boiler which appeared on page 213 of the July issue of THE BOILER MAKER. Mr. Hemingway's assumptions with respect to the strength of the longitudinal seam of the boiler which exploded are substantially correct.

There is no doubt that the pressure carried was in excess of that permitted by modern practice regardless of whether the staybolting of the firebox or the riveting of the vertical seam be considered, but it was the firebox failure which resulted in the destruction of the boiler and which was the subject of the July article although the seam construction may not have received the attention due it. Considering the strength of the seam in connection with the explosion which resulted from the failure of the firebox is somewhat like testimony which was presented in a murder trial. The fact that the defendant disliked his mother-in-law and abused his wife was not considered competent and did not furnish proof of his guilt or innocence of the murder, although his domestic relations may not have been all that they should have been.

However, as the boiler design was faulty and the pressure carried was considerable in excess of the safe limit, the explosion is just what might have been expected.

### SAFETY OF SECOND HAND BOILERS

On account of the immense building program and the highway construction activity being carried on at this time, small vertical tubular boilers are in great demand, so the second hand dealer can depend on a "quick turnover."

Such boilers used in construction work are seldom under insurance inspection supervision. Some of our states have no boiler laws, others exempt from the law boilers used in road and railroad construction work, boilers used exclusively for agricultural purposes and boilers used in the oil fields. Then, too, a portable boiler may be used for some time before those in authority and having jurisdiction may have any knowledge of its presence, as any legal requirement giving the owner the duty of notifying the state inspection department of the location of such a boiler is often not taken very seriously. So there is a great number of old portable boilers of the vertical tubular and of the locomotive types being operated without any inspection supervision and at pressures which sooner or later will cause failure of a more or less violent nature.

## REQUIREMENTS IN THE STATE OF MICHIGAN

At least one State Board of boiler rules (Michigan) requires the authorization of the transaction before a used boiler can be disposed of. This rule, adopted on June 15, 1922, is found in Appendix 3 of Paragraph 3 of the 1923 edition of the Michigan Boiler Rules and is as follows:

"No person, firm or corporation shall sell or offer for sale any second hand boiler for use as a steam boiler without authorization from the Board of Boiler Rules, Department of Labor and Industry."

The Michigan Board of Boiler Rules has also the authority to formulate regulations requiring persons, firms or corporations doing boiler repair work in the state of Michigan to report to the Board of Boiler Rules on such work that "repaired boilers may be properly inspected and the public safety thereby assured."

For various reasons it is not possible to have rules of this kind applied in every state of the union and as laws do not stop all theft or murder, there will be some evasions which may be discovered only after the explosion occurs and it was the purpose of the article appearing on page 213 of the July issue of THE BOILER MAKER to bring the repair shop's attention to the work they may do toward improving conditions as much as possible, although the practice of having a commissioned inspector examine the boiler thoroughly while repairs are under way is a good one, it cannot be followed in case there is no boiler law or where boilers of the type to be repaired are not under the state's jurisdiction.

Reverting to the exploded boiler and the strength of its furnace we must bear in mind a minimum plate thickness of 5/16 inch is now required so the code rules for determining the pressure which would have been approved on the boiler in question do not apply, but in order to avoid any misunderstanding which might result from Mr. Hemingway's furnace calculation I would call attention to the fact that it is not permissible to add the strength of the stays, as determined by 1918 Code, Paragraph 220c and Table 5, to the strength of the unsupported furnace sheet as determined by the calculations outlined in the 1918 Code, Paragraph 239a and b. Code interpretation 256 indicates a furnace in excess of 36 inches in diameter in a vertical firetube boiler must be stayed as a flat surface, and Code interpretation 277 refers to the use of Table 4 and Paragraph 212c in discussing the same subject. However, in the 1918 Code Paragraph 212c was nullified by the Code Committee (see Mechanical Engineering, February, 1921, page 139), and new paragraphs to appear in the 1922 revised code, as paragraphs 212c and 212d are being used. The revised paragraphs referred to make some allowance for the curved sheet's ability to resist collapsing stresses but not to the extent of the pressure which would be permitted on an unstaybolted furnace when calculated by Paragraph 239.

The cause or causes of the corrosive action which decreases the thickness of steel plates from the water side have been the subject of considerable research and much discussion; and there continues today about as much difference of opinion as when the action was first observed. There seems to be a pretty well founded opinion that the grooving around staybolt holes is in a measure the result of the stresses set up in the plates by the hole punching process. The reamer end of the staybolt tap cannot be depended upon to remove all of the affected material. No doubt the stresses due to temperature and pressure changes contribute their share but feed water conditions are undoubtedly responsible for the action which weakened the furnace sheet of the vertical tubular boiler which exploded at Algoma. Wisconsin, and similar conditions have affected a considerable number of boilers of that description which, however, had sufficient stays to provide an ample margin of safety to prevent a violent failure of the furnace before the leakage at the staybolt end gave warning of the sheet's weakened condition. This corrosive action is quite common where water containing considerable sulphur—from the coal mines for instance—is used.

Chicago, Illinois.

J. P. MORRISON.

## BUSINESS NOTES

John E. Cunningham, Jr., has been appointed assistant manager of the production department of the Schenectady works of the General Electric Co.

R. W. Benson, eastern representative at New York City of the Flannery Bolt Company, Pittsburgh, Pa., has resigned, and the company has closed its eastern office at 41 East Forty-second street, New York City.

F. Lee Townsend, formerly assistant boiler engineer at the Delaware Station of the Philadelphia Electric Co., has accepted a position with the Westinghouse Electric & Manufacturing Co. at the Philadelphia sales office.

The American Car & Foundry Company has purchased a tract of land 260 feet by 1,931 feet extending from the south branch of the Chicago river almost to Blue Island avenue and fronting on Wood street, Chicago, from the Edward Hines Lumber Company.

Graham Bright, formerly General Engineer in charge of the coal and metal mining activities of the Westinghouse Electric & Manufacturing Company, has joined the firm of Howard N. Eavenson & Associates, mining engineers of Pittsburgh, Pa. Mr. Bright will give special attention to power house systems, power plant appraisals, transportation and transmission systems for coal and metal mines, and general industrial power applications.

A number of changes have been made in the personnel of the district offices of the Westinghouse Electric & Manufacturing Company. A. D. Stewart has been appointed branch manager of the Butte, Mont., office, succeeding R. J. Cobban, who has been transferred to the Seattle office. L. C. LaMont has been appointed office manager of the Los Angeles office, succeeding J. R. Deering who has resigned. A. G. Crocker, formerly special power representative, has been appointed manager of the industrial division of the Detroit office, succeeding E. A. Wooten who has been assigned to other work.

## Locomotive Shipments and Orders on Hand

The following table was prepared by the Department of Commerce showing July shipments of locomotives from the principal manufacturing plants, based on reports received by the Bureau of the Census from the individual establishments:

	Locomotives		Seven months' total January to July		
21.1	July. 1923	June, 1923	July, 1922	1923	1922
Shipments: Domestic Foreign	$\overset{211}{_{28}}$	$221 \\ 11$	122 6	$1,543 \\ 101$	$\frac{34.2}{148}$
Total	239	232	128	1,644	490
Unfilled orders (end of morth) Domestic Frieign		1,854 164	712	:::	
Total	1,738	1,958	811		

### **Boiler Inspection Act**

The Circuit Court of Appeals, Sixth Circuit, holds that, while the Interstate Commerce Commission is authorized to make rules and orders in furtherance of the enforcement of section 2 of the Boiler Inspection Act, requiring boilers in operation to be in proper condition, the failure of the Commission to make a rule or order covering every defective condition or construction within the meaning of the section does not relieve the railroad from complying with its provisions.— Baltimore & Ohio v. Groeger, 288 Fed. 321.

## TRADE PUBLICATIONS

RIVET FORGES.—A 4-page illustrated bulletin, No. 504, describing a new suction feed type Venturi fuel oil-burning rivet forge, has recently been issued by the Hauck Manufacturing Company, Brooklyn, N. Y.

ZINC ROOFING.—The New Jersey Zinc Company, New York, has issued a small leaflet outlining the adaptability of standing-seam Horse Head zinc roofing for many types of buildings. The leaflet is illustrated with sketches showing how the roofing is applied.

PORTABLE OIL HEATERS.—A 16-page illustrated bulletin, No. 503, describing the latest Venturi oil-burning torch for making locomotive steel car and rip track repairs, has recently been issued by the Hauck Manufacturing Company, Brooklyn, N. Y.

ALTERNATING CURRENT MOTORS.—The Reliance Electric & Engineering Company, Cleveland, Ohio, has just issued a 14-page illustrated bulletin, No. 5018, descriptive of its new line of Type AA induction motors for two and three phase alternating current circuits. These motors, which are of the squirrel cage type, range in sizes from  $\frac{1}{2}$  to 25 hp., and in speeds from 900 to 1,800 r.p.m.

RIVETERS.—The Hanna Engineering Works, Chicago, has recently issued a 64-page illustrated booklet, Catalog No. 5, fully describing the design and construction of its compression yoke riveters, which range in sizes from 4 in. to 21 ft. reach, and in capacities from 10 to 150 tons. These riveters are particularly adapted for use in the boiler, tank, structural, bridge, car, and steel shipbuilding industries.

A TEST OF INTEGRAL WATERPROOFING.—In an eight-page folder issued by the Truscon Laboratories, a report is presented of tests made by Samuel R. T. Very, architect, on the increased impermeability of concrete containing an integral waterproofing compound. The report is presented in an entertaining way with no similarity to the exceedingly prosaic style commonly used in reporting such tests. The conclusions obtained are also presented in a concise way so that the busy reader has no difficulty in getting at the fundamental facts. As pointed out in the report, the tests were conducted so as to approximate as nearly as possible the kind of workmanship commonly obtained in actual concreting rather than that secured under laboratory conditions.

OIL STORAGE SYSTEMS .- An attractively prepared bulletin containing 49 8-in. by 10-in. pages devoted to oil storage systems has been issued by S. F. Bowser & Co., Inc., Fort Wayne, Ind. This bulletin is intended primarily for reference by railroad men who have to deal with the pumps, tanks and devices used in storing or handling oils, gasoline and other liquids. Clear-cut illustrations in color accompanied by appropriate descriptive data are given in various parts of the equipment, including agitators, agitator tanks, barrelfilling equipment, carload storage tanks, gravity-filling devices, measuring systems, oil pumps, mixing tanks, selfmeasuring pumps, signal oil pumps and out-pits, and many others. Several interesting illustrations are included of oil supply cars which are now in satisfactory service, effecting important economies in handling and supplying oils to outlying points. The bulletin explains the advantages of Bowser equipment in economy, convenience, safety, dependability and long service.

## SELECTED BOILER PATENTS

Compiled by

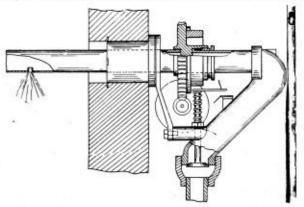

GEORGE A. HUTCHINSON, Patent Attorney,

Washington Loan and Trust Building Washington, D. C.

Readers wishing copies of patent papers, or any further information regarding any patent described, should correspond with Mr. Hutchinson.

1,465,387. BOILER CLEANER. FRANK BOWERS, OF DETROIT, MICHIGAN, ASSIGNOR TO DIAMOND POWER SPECIALTY COR-PORATION, OF DETROIT, MICHIGAN, A CORPORATION OF MICHIGAN.

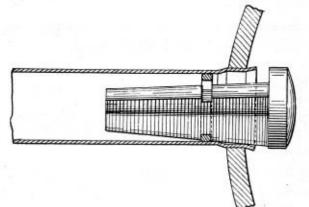

Claim 1.-In a boiler cleaner, the combination with a rotatable blower unit adapted to discharge steam jets or the like, a stationary supply pipe,

a valve therein independent of the blower unit, means to rotate the blower unit, and a rotary connected to said unit rotating means and arranged to operate said valve to automatically supply steam or the like from said supply pipe to said unit while the jets are directed toward predetermined portions of the boiler. Three claims.

1,465,118. MEANS FOR REGULATING WATER CIRCULATION IN WATER TUBE BOILERS. SAMUEL E. DIESCHER, OF PITTS-BURGH, PENNSYLVANIA.

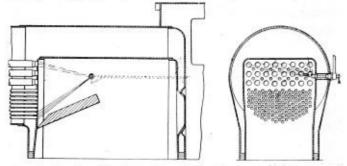

Claim 1.-A flow restricting plug for boiler tubes having three substantially equally spaced and radially extending tube engaging fins, each having

a slot therein and a snap ring located in said slots and adapted to engage the inner face of the tube when the plug is in place in a tube. Three claims.

1,463,250. LOCOMOTIVE BOILER. JOHN J. CAIN, OF BAYONNE, NEW JERSEY.

Claim 1.-A locomotive boiler, comprising similar narrow hollow vertical sections, having supporting feet at their lower edges transversely arranged

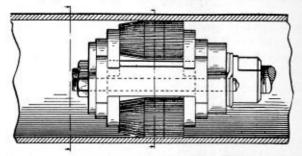

edgewise in pairs with their adjacent edges at the longitudinal central plane of the boiler and spaced apart to provide continuous vertical heating passage between them, the boundaries of the transverse faces of each pair

being substantially equal to the vertical and transverse horizontal boundaries of the available space of the locomotive above its running gear, said duplex sections being in two sets longitudinally located in the boiler, the lower parts of the sides of the set of sections at the furnace end of the boiler being water legs and constituting the side walls of the fire box with their supporting feet at a lower level than those of the other set of sections, in combination with the main frame of the locomotive to the side girders of which the supporting feet of the sections are secured. Eleven claims.

1,463,587. BOILER-TUBE CLEANER. ALBERT F. KRAUSE, OF BUFFALO, NEW YORK, ASSIGNOR TO GENERAL SPECIALTY COMPANY OF BUFFALO, NEW YORK, A COPARTNERSHIP.

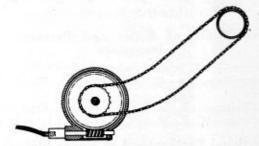

Claim 1.--A boiler tube cleaner, comprising a rotatable head, a cutter, a member carrying the cutter and movably mounted on said head, said

carrying member extending across and on opposite sides of the head, and controlling means for causing said carrying member to move in the direction of its length on the rebound of the cutter. Nine Claims.

1.462.415, APPARATUS FOR CLEANING THE OUTSIDE OF BOILER TUBES. FRITZ KOBER, OF SUHL, GERMANY.

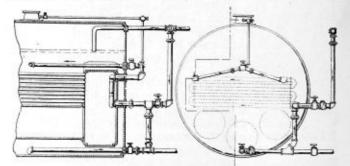

Claim 1.-An apparatus for cleaning the exterior of boiler tubes, comprising a portable operating mechanism, and an endless band or chain

having cleaning tools and operated by said mechanism, said band or chain being adapted to be passed around the tube to be cleaned. Two claims.

1,463,933. MARINE BOILER. RICHARD WALSH, OF MOBILE, ALABAMA.

Claim .-- In a boiler, a heater coil, a pipe extended within the lower portion of the boiler and provided outside the boiler with a valve, a pipe connected with said pipe, a pipe rising from the last-named pipe, a lateral

branch therefrom connected with said coil, a pipe leading from the upper part of the coil, an upwardly-extended pipe leading from the last-named pipe and having a lateral branch with a valve, a pipe connected with said branch and extended within the upper part of the boiler below the water line, a steam pipe connected with the steam dome and with said branch and provided with a valve, a pipe extended upwardly and connected with the boiler and having means for connection with a feed pump, and a three way valve controlling the flow from the feed pump, the flow to the boiler, and the how through said pipe to the heater coil.

### 1.458,582. FURNACE AND BOILER CASING. CHARLES R. KLINE, OF READING, PENNSYLVANIA.

Claim 1.—In a device of the character stated, a casing for boilers, furnaces and the like composed of metal sheets lined on their interior with non-conducting material, a boiler in said casing having a door, a door opening in said outer casing sheet aligning with said boiler door, and a casing door closing said opening and hinged to said outer sheet, the inner surface of said casing door being provided with a lining of non-conducting material and the inner surface of said boiler door being also provided with a lining of non-conducting material, and an outer projecting member surrounding the opening into said boiler, said member being adapted to be embedded in the non-conducting material of said boiler door when the door is closed. Two claims.

# THE BOILER MAKER

OCTOBER, 1923

## The Dürr Boiler Works at Ratingen, Germany

By Captain Godfrey L. Carden*

Industrial conditions in Europe, especially in Germany, are not well understood in this country—and yet there are many phases of the situation that are of special interest to manufacturers and men in the shops. Captain Carden in the following article explains the status of boiler design and construction in one of the largest shops in Europe devoted to boiler work and outlines the tendency in design towards higher pressures and changes in types. The picture given of work at this plant reflects to a great extent conditions throughout Germany.

HE Durr boiler works at Ratingen, near Düsseldorf, is representative of the best in the boiler industry in the German Rhine-Boilers of the land. Durr type were shown in the power installation of the St. Louis Exposition. Those particular boilers were of the marine type, and were part of a group for a German cruiser. The writer speaks advisedly on this point since he collected these and other foreign boilers as used at St. Louis.

I revisited the Durr Works today. The correct name of the plant now is "Düsseldorf-Ratingen Rohrenkesselfabrik Vormals Durr &

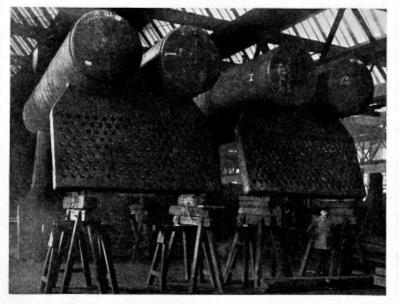

Fig. 1.-Completed Boilers at the Dürr Works

Company." My talk was with director Loch, by whom every courtesy was extended.

### LARGE STAFF OF MEN EMPLOYED

Here is a boiler making works employing as many as 1,000 men when working to capacity, and now carrying on the pay rolls 650. All work in the plant ceased September 12. No more raw material available and the impossibility of transporting products under the French occupation is responsible for the shut-down.

The Durr Works have orders ahead for nearly a year. These orders include both export and home fields. Nothing can be done to fill these orders until conditions change in the Ruhr and Rhineland. The same situation applies to all most intensive iron and steel and machinery-producing centers in all Europe.

## FOREIGN ORDERS RESPECTED BY FRENCH

Up to today the Durr Works continued to build equipment to meet orders in hand, the idea being to deliver such equipment whenever conditions warranted it. The French have respected foreign orders received before the occupation, but material produced subsequently has been subject to reparations demands. The result is that many German shops in the Ruhr and Rhineland which were building to stock do not know today if they can make delivery. They must first learn the French intentions as regards their goods.

The Durr Works has installed some of the largest power stations in Germany. Even with the shops shut down the engineering staff is hard at work on designs and improvements. Marine boiler work ceased with the close of the war and the Durr people are now paying attention almost wholly to the land installations. Boilers working at 34 atmospheres

French occupied regions. No items may be sold and exported without a French license. The German government has forbidden its nationals to pay these licenses. The German manufacturer must choose between the French and his own government. He prefers the latter. The result in Ratingen has been that not a train whistle has been heard in that town in six months. The weeds and grass are growing on the railroad station platform, the rails are rusted, the station buildings abandoned; and it should be borne in mind that Ratingen is a unit in what is one of the

German works in the

^{*}Captain Carden is an officer of the United States Coast Guard. He early saw service in Europe collecting boilers and engines for the power plant of the St. Louis Exposition. Later he served for two years for the Department of Commerce at Washington reporting on iron and steel and machinery and machine tool work on the continent of Europe. In that period he covered a wide range of territory, and gained first hand knowledge of conditions at several hundred of the first shops of the world.

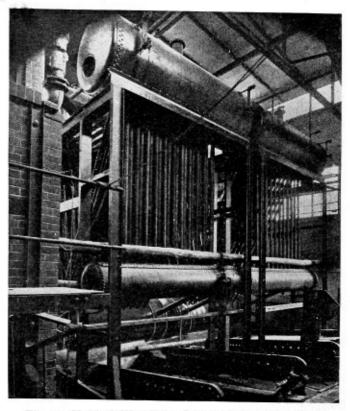

Fig. 2 .- Vertical Wet Tube Boiler Made at Esslingen

pressure (about 500 pounds) are the standard type, but boilers to work under 60 atmospheres (about 880 pounds) are also built.

### TYPES OF BOILERS BEING BUILT

The Durr boiler is generally built with two drums, above and below. Boilers with only one lower drum are used for small units and small capacities and chiefly for utilizing the waste heat from Siemens-Martin and annealing furnaces and coke ovens. The newest Durr boiler is distinguished by its use of Garbe plates and vertical tube nests with straight tubes. The standard capacity of these boilers is rated at 25 to 35 kilos (about 55 to 72 pounds) each hour per square meter (10.76 square feet) of heating surface. Under forced service this capacity may vary from 35 (about 72 pounds) to as high as 50 (about 110 pounds) kilos.

The boiler sizes range from 30 up to 2,000 (about 323 up to 21,450 square feet) square meters total heating surface. Until comparatively recently very few boilers were made in Germany for land service having more than 1,000 (10,764 square feet) square meters' heating surface.

### LIMITS IN SIZE OF BOILERS

The rule has been to keep the sizes under 600 square meters, and, therefore, we find the 600 (about 6,460 square feet) square meter-boiler the size most commonly in use. The current opinion held among German engineers, that the big boiler with a heating surface of over 2,000 (about 21,450 square feet) square meters, such as seen in America, was not suited to German conditions where the power requirements and available fuel are somewhat different.

In my talk with director Loch I learned that boiler work in Germany had been very much advanced in the past year through a more general recourse to vertical tube boilers. When vertical tube boilers were first offered on the market in past years there was no success. This was due in part to the serious opposition of competing systems. The principal defect with the first vertical tube boiler was the fire vault over the grate. There was always danger of falling in after

service under long working periods. The first steep-tube boiler yielded wet steam, resulting in frequent disturbances in the steam turbines. In the case of the fire vault the design has since been changed so that now the length corresponds more to the American ideas. According to director Loch the Sterling and Garbe boilers have taken the lead in Germany in the past year. The original Garbe has been taken over by the Durr Works and improved upon. The Garbe boilers are entirely without welded or pressed headers, staybolts or pipe closes. The Garbe plates are pressed, corrugated and step shaped. No tightening of the tubes is necessary, the tubes are arranged in straight rows. There is easy accessibility to the back rows. Under the vertical arrangement there is no chance for mud to be deposited in the tubes. The mud collects at the lowest point in the lower drum from where it can be blown off.

The Durr Works have made installations for some of the largest power units in Germany. These include the power plant at Golpa, which plant is at present supplying the electric current of Berlin, the Goldenberg Works of the Rheinisch-Westphalien Electrikal A. G. located in the Rhine brown coal district and the Amoniac Works at Merseburg. All of these installations have the steep-tube boiler and are fired with low grade brown coal.

#### ADAPTABILITY OF STEEP-TUBE BOILER

It has been found that the steep-tube boiler is well adapted for service under lignite firing with the attending dust which characterizes that fuel. The ashes do not accumulate on the steep inclined water tubes, and the heating surface is unimpaired. Similarly, there has been a turning in the recent past, says director Loch, to the riveted water chamber, because of boiler explosions occasioned by the tearing off of the welding line of chambers.

The marked tendency today, it was declared, is towards higher boiler pressures. The "Atmos" 100 (about 1,470 pounds) atmosphere pressure boiler is being built in Germany, in Madgeburg at the Sudenburger Maschinenfabrik und Eisengiesserei. This is a Swedish design, the parent house being located in Stockholm. In the Atmos, revolving tubes are used, turned by electric drive. In case the motor drive should stop, the danger from explosion is taken care of through providing the tubes with fusible plugs which fuse when the temperature of the tubes rises to about 400 (about 752 degrees F.) degrees Centigrade. The steam thereby escapes into the furnace, serves to cool the brick work, and thus prevents any bending of the tubes. Under the same arrangement, the safety device functions if a tube should be empty of water by incrustations in the inlet tube.

#### HIGH PRESSURES ADOPTED

Among the German boiler makers a conference was held in June, 1921, at Cassel, at which time director Hartmann of the Schmidt Hobsteam Company spoke of the great economy obtained from high steam pressures of say 60 (about 850 pounds) kilograms working pressure. Up to this time no plants in Germany were using such pressures. What is now common is the 30 to 35 (435 to 506 pounds) kilograms pressure boiler. Under the present tendency the pressures are to be advanced to 60 (about 850 pounds) kilograms and for such pressures the lower and upper drums of the Durr and similar type boilers will be forged from one piece, after the Krupp process and using Krupp steel. It is believed that the 60 kilograms (850 pounds) pressure boiler is more in keeping with conservative ideas than the 100 kilograms (1,447 pounds) boiler. The latter type as made by the Magdeburg firm has, I understood, tubes of 305 millimeters (about 1.20 inches) outside diameter, 10.5 millimeters (about 0.413 inch) wall thickness and 2,500 millimeters (about 5.28 feet) of gas contact length. The tubes revolve with a speed of 330 revolutions per minute. By means of centrifugal

Fig. 3.-Assembling Boilers at the Dürr Shops. Garbe Plate in Foreground

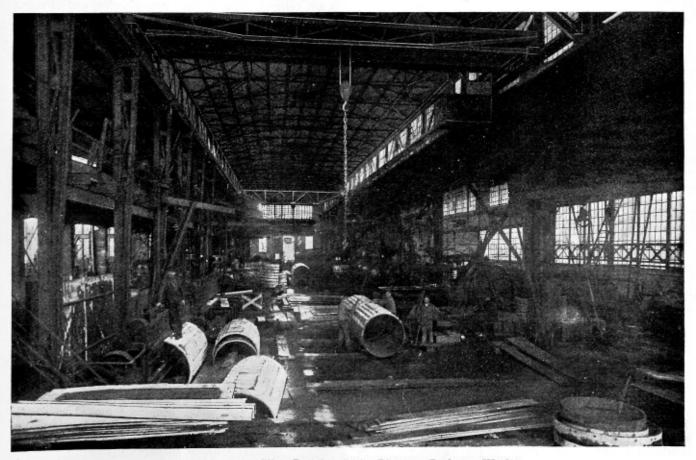

Fig. 4.-Assembling Bay for Garbe Plate, at Ratingen Works

power a water jacket is pressed to the internal heating surface. The tubes are revolved by tooth gearing, electrically driven.

### DIFFICULT TO OBTAIN FUEL

Just now because of the Ruhr occupation and the shutting off of fuel from the unoccupied territory, coal of good quality is very difficult to obtain in Germany. Recourse has been had to England and Moravia, but in the main Germany has turned her attention to the brown lignite fields. This is a low grade fuel and those power stations which heretofore used first-rate coal must now be satisfied with low grade fuel. For the firing of this brown lignite coal it is found that the normal, not the mechanical, step grate is the more advantageous. As director Loch put it, the general view held in Germany today is to work designs best adapted to our low grade fuel, and which designs will offer the maximum of freedom from boiler explosion.

## Scale Formation and Its Prevention

## British Experience in Using Boiler Compounds and in Eliminating Boiler Difficulties Caused by Hard Water

## By T. Sington

A N eminent English expert has recently expressed the opinion that there is no "short cut" in water softening to prevent boiler scale. A steam user burdened with hard water has only one course open to him, should he really desire to avoid coal waste and boiler damage, that is, to soften the water in accordance with well-known reactions in a properly designed apparatus, before it is fed to the boilers. Should he do so he would get the maximum result at a minimum cost; but should he pin his faith to boiler remedies, he would obtain the minimum result at the maximum cost and, in addition, incur the risk of damaging his boilers into the bargain.

The following analyses of some boiler compounds widely sold in England illustrate the worthlessness of these and indicate the profit, by no means on a modest scale, at which they are sold to the consumers:

(A) Sold at \$0.72 per gallon: Water, 97.50 percent; sodium carbonate, 2.50 percent; tannin extract, 0.20 percent; sugar and others, 1.42 percent.

(B) Sold at \$0.48 per gallon: Water, 97.50 percent; caustic soda, 0.70 percent; algin and others, 1.80 percent.

(C) Sold at \$2.40 per gallon: Water, 5.01 percent; chalk, 57 percent; mica, 31 percent; sodium carbonate, 6.99 percent.

None of these compounds, even if used in large quantities daily, could conceivably have any noticeable effect in retarding the deposition of scale by many waters now in use. Nevertheless, comparatively small concerns spend as much as \$1,000 per annum on one of them. Such firms could soften the whole of their boiler feed water to three degrees by the expenditure of only \$120 yearly, if they would employ lime and soda in a proper apparatus. Inspection of the boilers of these concerns showed that they were badly scaled, despite assurances that the fluid was used regularly and had given satisfactory results.

As many people who are in close touch with feed water problems are aware, the clearer comprehension by steam users of the simple chemical facts, which form the basis of all water softening methods has led of late years to a considerable decline in the sale of what may be called "quack" remedies for boiler scale.

### GUARANTEES RARELY OFFERED FOR COMPOUNDS

It is rare to find a boiler composition offered for sale under a guaranteed analysis. There is no mystery whatever about orthodox water treatment. If steam users would insist on knowing the percentage composition of the boiler compounds offered to them as remedies for scale and corrosion, there would be a rapid disappearance of these compounds from the market, as very few of them would survive the publication of their ingredients.

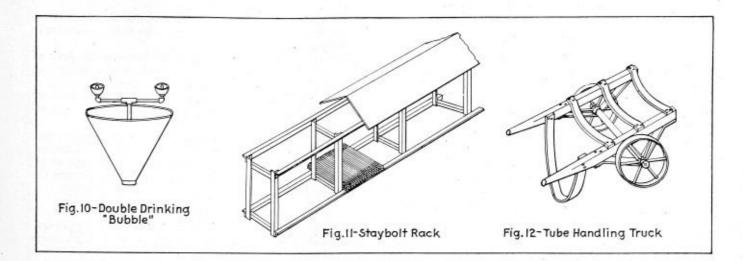

The direct treatment of the feed water in the boiler itself is only a matter for boiler plants of a very restricted size. In a boiler plant of any reasonable capacity the only thing to do, of course, is to install a softening plant, at any rate for water over 7 to 10 degrees in hardness and to take out the scale-forming elements before the water goes into the boilers. With a small installation, it may not pay to go to the expense of a softening plant. To quote an expert-"the desirability of pure water for boiler feed purposes is well known to every steam user and for the most efficient results it is necessary to have water certainly not over 5 degrees total hardness, together with freedom from substances such as air, carbonic acid, oil, salt, natural acids, and of course added mineral acids, such as sulphuric acid from pyrites in coal measures, which may cause corrosion. Hardly any natural water is absolutely pure and very few would comply with the above specification, so that for the advantage of the boiler plant, it is essential to treat the feed water. The trouble is, however, that with small or even medium sized boiler installations the initial expense of a softening plant and particularly the trouble of looking after it, together with the cost of lime, soda and of other material necessary is apt to be a somewhat formidable item.

Natural waters are rarely pure, the average hardness may be say 12 grains per gallon, that is, for every gallon evaporated, 12 grains of solid material are deposited in the boiler plant. Of course, individual waters vary greatly; they may contain anything from say 2 to 50 grains, but 8 to 16 grains is a reasonable average.

## Annual Fall Meeting of American Welding Society

THE annual fall meeting of the American Welding Society will be held in Pittsburgh from October 24th to 26th, 1923. A tentative program of the meeting follows this announcement.

A unique feature of this meeting will be the opening session on Wednesday morning. President Barton will present a general statement of the Society's affairs and an opportunity will be provided to all the members to discuss the activities and policies of the Society. While a good part of the work must necessarily be done by a limited number of committee members, nevertheless, the advice and assistance of the entire membership is needed and wanted at all times. (Continued on page 290)

# Time Saving Devices for Boiler Shops*

# Appliances and Methods That Various Shops Have Found Useful in Repair Work

# By James F. Hobart

N a trip to the Memphis shops of the I. C. Railroad the writer was shown the sections of apparatus for a double bubble drinking-fountain, a tube-handling truck and a stay-bolt rack illustrated in Figs. 10, 11 and 12. The drinking-fountain consists of two regular "bubble" drinking nozzles with porcelain covered guard cups which were open at the bottom and discharged into the galvanized metal oval funnel shown in the picture. The bubbles were connected by pipes and a tee to the same vertical pipe, and were located about 20 inches apart, giving room for two men to drink at the same time. The saving in time thereby can be appreciated, as it seems a fact, that whenever a man stops to take a drink of water, another man will come along and wait for the first man to get through. The double-bubble prevents much time being lost in waiting, for, although each wait is of but a few minutes' duration, it surely counts up in the aggregate during the day.

These bubbles are allowed to flow all the time, there being no valves for closing them off, save a main valve which is closed at night only. If iced or carbonated water were to be served, the bubbles could not be permitted to flow all the time, but in the I. C. shops, plain water was used for drinking purposes.

# STORING STAYBOLTS

Staybolts by the thousands are stored in the Memphis I. C. shop in such a manner than any size or lot, is instantly accessible. Little steel, open-side houses, 10 inches in width by 18 inches high from sills to plates, are provided in 5foot sections as shown by Fig. 11. The frame is made of 1¼-inch steel angles, the roof, of 10-gage steel.

A great many staybolts are made in these shops, and double staybolt threading machines, electrically driven, are provided for manufacturing staybolts in great quantities.

#### Some Interesting General Notes

The working floors of the boiler sheds are filled in with cinder to a depth of several inches, making a floor much

*Continuation of an article, "Home Made Appliances for Boiler Shops," which appeared on page 222 of the August issue of THE BOILER MAKER. softer than concrete. Each punch and shear is electrically driven by a motor which looks ridiculously small when compared with the size of the driven machines; but carrying power is obtained from a five-foot balance wheel, with a rim about 6 by 6 inches working upon the pinion shaft of each machine.

The punching and shearing machines in this shop are operated by colored workmen. Each machine is independently electrically driven and the bending rolls are reversed by means of overhead connections with the motor. A band, metal saw is something of a novelty in boiler shops but it is in use in this one.

# HANDLING BOILER TUBES

Boiler tubes up to five inches in diameter are cut off by a single wheel machine similar to an ordinary pipe cutter except that the cutter is stationary and the tube is revolved by power. Supporting the tube during the cutting-off process, are two small flat wheels or rollers, placed a short distance apart, but nearly opposite the cutting wheel.

Tubes are cleaned in a rumbler, which is located in a tight house—power and all—weighted vertical doors being provided for putting tubes in and out. The scale and dirt is removed through a cleaning door at bottom of the house. This arrangement keeps nearly all the dirt in the house, together with nearly all the noise.

Tubes are handled from boiler to shop and back again by means of little hand trucks, or two-wheeled barrows, made up as shown by Fig. 12. This vehicle, save for the wooden side-rails or handles, is built entirely of metal and surely is a rugged bit of construction. The cross bars are concaved as shown, to receive a batch of tubes and to keep them from rolling off the vehicle. The truck, or barrow, is held in nearly a level position by a loop or stirrup of bar steel, bent as shown, to reach to the ground. The workmen, in using this vehicle, never need but one lesson in regard to loading the tubes so as to "hang" properly. If loaded too far forward, the front of the truck cannot be raised from the ground. If loaded too heavy behind, the barrow lifts itself, and "sits down" with alacrity if not with elegance. But properly loaded, two men handle a load of tubes with considerable ease.

# PIPE FITTING AND BENDING

In an ice-plant repair shop at Vicksburg, Miss., they have a way of bending pipe whereby the pipe is first filled with water, a cap having been placed on one end of the pipe. Then, a "hydraulic fitting" is screwed upon the other end of the pipe and after having been carefully and completely filled with water to the exclusion of every particle of air possible, a plug is screwed into the hydraulic fitting, with result that considerable pressure is placed upon the water in the tube and the engineer of the plant told the writer that the pipe would "bend like lead," without flattening in the least. "And," the engineer continued—"you have tested the pipe too!"

In the I. C. shops at McComb, Miss., and in the T. & P. shops at New Orleans, they seem to be "long" on air cylinders, which look very much like the old-time steam brake cylinders which used to do such good work on locomotives before air brakes came into use. A lot of these cylinders, operated with air, have been put to use in both the shops mentioned above, in the operation of "home-grown" tools.

A pipe-fitting and bending table or bench in the I. C. shop has two such cylinders for operating pipe vises. This pipe-bench, which is a "dandy" is represented at A in Fig. 13. The top of the table is a massive metal plate which is supported on stout timbering as shown at B, into which are framed several stout legs C, C, and one very much stouter at D, to which is attached an enormous vise E, by means of heavy metal straps and bands F and G, in a manner so strong and rigid that it is almost impossible to pull the vise away from its fastenings, particularly as the bench-posts are let into the concrete floor of the room.

A pipe-bending plate is attached as shown at H, being made fast to the top of the bench. A large number of holes, I, I, have been drilled through plate H, and pin K, and sheave J can be juggled around from one hole to another until they are in proper position for bending any curve required in pipe for fitting up boiler connections.

There are two pipe vises with this bench, and they are both unique as well as home-made. The smaller vise, located at L, is bolted fast to the bench-top and this vise has a movable jaw which is attached to lever M, which in turn is connected to, and operated by air cylinder O, which seems to be one of the before mentioned, discarded steam-brake cylinders.

Whenever a piece of pipe is thrust between the jaws of vise L, and air turned into cylinder O, it is a pretty safe bet that the piece of pipe will stay between the jaws without turning, as housing N, is bolted to the bench too strongly ever to be torn away by air-power in cylinder O, or manpower on a pipe in vise L.

Another pipe vise at P, is a much larger and stronger one. Its lever Q, and housing R, are strong and massive. Cylinder S develops power enough, with the leverage of Q, to hold fast pipe of any size which can be put between the pipe-vise jaws.

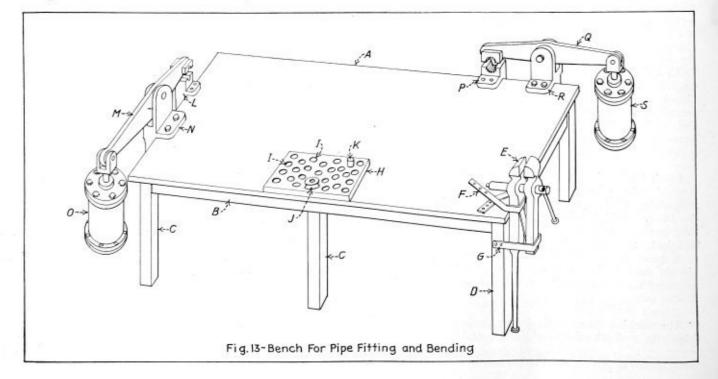

#### AIR-OPERATED SHEAR

Several machines almost similar in their method of operation, to the pipe-vises, are to be found in the T. & P. shops (Texas & Pacific) at New Orleans, and the same utilization of obsolete steam brake cylinders is apparent. In Fig. 14, it is shown how shear-lever A is mounted in housing B and carries shear-jaw C which members with a similar jaw Dwhich in turn is bolted fast to casting E and both members made fast to base-timber F.

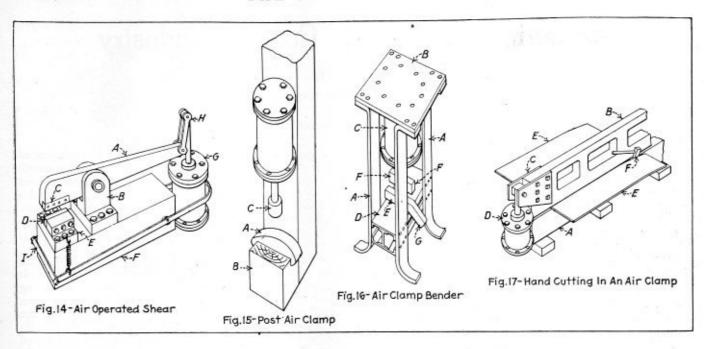

The shear is operated by air-cylinder G, to which lever A is attached by means of the link arrangement at H. Treadle I operates air admission and exhaust to and from cylinder G, and thus controls the action of this rugged home-made shear.

#### POST, AIR BENDING CLAMP

A very handy and frequently used appliance for bending narrow rod or bar steel, also some pipe, in the T. & P. shops, is shown by Fig. 15. The engraving shows the appliance so clearly that little description is necessary save to say that a sort of anvil-mold A, of shape required for the work in hand, is placed upon block B, the form being notched in this instance, to fit over the block. The metal to be bent, being heated and placed upon A, head C is forced down by airpressure in the cylinder and the object is held securely upon form A while being sledged down to fit thereupon, or to the angle desired. A variety of shaped forms may be used upon block B, which is made of such height that plunger Ccan always reach the work without exceeding in lengthmovement, the length of the air cylinder.

A machine which is portable in the sense that it may be carried to the work by the shop crane is shown by Fig. 16 herewith. This machine is made much upon the principle of the one last described, save that instead of being attached to a post, stress is borne by the four leg-posts, A-A, which in turn are bolted to top plate B, which also carries air-cylinder C.

The anvil of the appliance, D, is built up of channels and an I-beam. To this anvil may be attached any former or die, as E, upon which members another die or former F-F, which is attached directly to piston rod of the air cylinder C. In this instance, former E is shown elongated and bent down at an angle at G. After the stock to be bent has been smashed into shape between formers E and F, it may be further sledged down against extension G, as may be required.

# Welded Joints in Unfired Pressure-Vessels*

"HE tests which have recently been conducted at the Bureau of Standards have in our opinion justified in a great measure the claim made by the welding fraternity. These tests have also justified and confirmed the conclusions already drawn by The Travelers from a review of the experience with welded, unfired pressure-vessels now in service-this experience representing over 10,000,000 tankyears. The Travelers is, of necessity, conservative, and we have been slow and reluctant to join in any movement urging the inclusion in the A. S. M. E. Pressure Valve Code of requirements which would permit fusion welding. We have felt the need for just such facts as are now available through the series of tests conducted at Washington; but for our own purposes-that is, for insurance purposes-we have felt that such additional proof was not a necessity. We are governed by federal, state and municipal laws wherever they apply effectively; but in many cases these laws do not apply to unfired pressure-vessels, whereas insurance is universally applicable.

We are now insuring, and have insured in 1922, pressure-

A couple more old steam-brake cylinders have been put to use in the T. & P. shops by being attached to a big, husky bending clamp. Only one of the cylinders is shown at D, in Fig. 17, the other cylinder not being shown in the engraving, in which A represents the lower member or jaw of the press, and B, the upper or movable one. A pair of extension plates C, attached to B, forms connection with the air-cylinder D.

At the time the writer saw this modified tool, a couple of workmen were doing a job of hand sheet-cutting with it. Plate E-E had been put in position to be cut along the side of jaw B. One man took a cold-cutter and held it as shown at F, the other man striking the cutter with a sledge. The lower clamp-jaw A, formed with cutter F, a shear which severed plate E very smoothly.

vessels of many kinds and at varying pressures—vessels having their longitudinal (as well as their girth and head seams) fusion-welded. We are satisfied now, and we were satisfied before these recent tests were made, that fusion welding can be made insurable. Our experience with it has been satisfactory, and we expect to continue to insure welded vessels with equally good results.

Fusion welding is an art which has certainly come to stay, and we believe that we can best serve the interests of the public, and assist to a greater degree in the safe development of welding practice, by working with the welders, with the manufacturers, and with the various engineering societies authorized to establish rules and regulations, as far as we can consistently do so.

When fixing, for insurance purposes, the safe working pressures of fusion-welded unfired pressure-vessels, we have been arbitrarily assuming (pending more definite methods of determining the ratio of the value of the weld to the value of the solid plate) a joint efficiency of 50 percent. We further reserve the right, as does any insurance company, to accept or reject any or all tanks, either before or after inspection. The point I wish to bring out is, that we do not consider a tank uninsurable, merely because it is fusion-welded.

As a result of the data now available, and submitted by the Bureau of Standards, there is no reason why a good (Continued on page 283)

^{*}Remarks by H. W. Heinrich, Engineer, of The Travelers, at the Welding Conference, New York City.

# Measuring Production Costs in Industry

# The Key to Correct Costs—The Necessity of Using Accurate Cost Methods

# By William R. Basset*

T takes but little skill to determine exactly what the labor and material in a product cost, for these can be accurately measured with but little effort. Overhead expense is not so easily measured. It is inaccurate allocation of overhead that causes most inaccurate costs.

The pity is that the man who has an elaborate cost system may be getting wrong information from it, while believing that his cost figures are trustworthy. He who has no figures is better off than he who has wrong ones, for at least the first man knows that he is merely guessing.

#### GENERAL RULES FOR KEEPING COSTS

No one method of getting overhead into the product will do for all industries nor for all concerns in an industry, but the same methods of gathering the costs fit all. Here are the fundamentals of correct accounting for overhead.

 Gather overhead, not for the plant as a whole, but for each department separately.

Charge the overhead of a department only to those items of production that are operated upon in that department.

3. Overhead is a charge that the product must pay to a department for the use of the facilities furnished by that department. These facilities may include floor space, heat, light, power, supervision, non-productive labor such as truckers and janitors and perhaps a rental for the use of machines. Therefore, it is important to determine a way to measure in dollars the use that the product has made of these facilities. It may be measured differently in every department. In one the man hour may be correct, in another the machine hour, the payroll dollar and so on. To determine the unit is a job for someone fully acquainted with the problems in the plant.

In plants where overhead is incorrectly spread over the product I have seen cases where costs were 50 percent and more off. Some were too high and others too low by that much. Such a condition makes business too much of a gamble.

# SETTING THE SELLING PRICE

Of three uses to which cost figures can be put, most concerns use only one—and that one the most obvious. They use it as a basis for setting a selling price in normal times.

When business falls off in a depression they commonly either throw the whole system overboard in the effort to cut expenses, or they utterly ignore the figures.

Now anyone knows that it is better in an emergency to sell at a price which although below cost, will keep the plant going and bring back part of the unavoidable overhead, rather than to shut down and lose all of the overhead. But without figures which show all of the items of cost accurately, there is the danger that a price may be set so low that the losses will be greater than if the plant were shut down. Nothing is gained unless the cut price brings back the cost of labor and material and a certain part of the overhead expense.

Properly developed costs show just where that point is.

The other seldom used feature of a cost system is its ability to show where costs of operation can be cut—where, in other words, the efficiency of the plant can be increased. The cost system is the most effective indicator of where betterments can be made.

* President, Miller, Franklin, Basset and Company, Inc., New York City.

In one plant a new cost system showed that the usage of dyeing and bleaching materials fluctuated widely from month to month. This led to a study of the methods, which showed that the solutions were not based upon scientific formulas but upon the guess work of a none too skillful foreman. Standards were set for all solutions with the result that the usage of dyeing and bleaching materials was cut about \$18,000 a year.

In a machine shop a sudden rise in the use of lubricating oil for automatic machines was shown by the cost system. It came out that an inferior quality of light oil was being bought by the purchasing agent. This oil, under pressure, went through the machines so fast, that not only was the monthly cost for oil higher, but the lubrication was insufficient and had the practice not been stopped, a hundred thousands dollars' worth of machines would have been badly damaged.

The wise executive carefully studies his cost figures to spot inefficiencies such as these.

# How BIG SHOULD THE PLANT BE?

Closely allied with the problems of overhead and cost systems is the question of the best size for a business.

Almost every man feels that if his business were only larger, his profits would be greater and all would be well. A business man's career is usually a continuous struggle to make greater sales and to make his plant larger.

Undoubtedly the manufacturing of the future will be done by the large enterprises for only they can achieve the economies of mass production. But it does not follow that it will be done in tremendous plants, centralized in one location. Far-sighted business men and engineers realize that the big plant is not always the most economical one either for making or for selling.

There is a best size of manufacturing unit for each industry. The big business will have many such units spread over the country.

If a plant is too small it cannot afford to pay the price demanded by men capable of manufacturing economically for it cannot utilize all of their ability. It must put up with inferior, cheaper talent.

If on the other hand the plant is too large, executive supervision will not be able to cover it completely. There will be a fringe that will escape proper supervision. That means that something or other will constantly be going wrong.

To determine just how large your plant should be, for best results, is a study that will well repay the effort and time taken.

# Maintaining Oxy-Acetylene Equipment

THERE is probably no class of equipment used in mechanical plants which receives so little proper care as welding and cutting apparatus. It is so easy to maintain such equipment in good operating condition and the results of such maintenance represent so great a saving in gases and efficiency that the little care necessary pays for itself many times over. There is nothing more exasperating to an operator than a torch or a regulator which is in bad condition. He cannot properly maintain a neutral flame and his torch may be constantly flashing back, all caused possibly by a little dirt in the torch or a leaky regulator.

# Making Charcoal Iron for Boiler Work

Development of the Manufacturing Process with an Outline of the Qualities of Charcoal Iron

By G. A. Woodroffe*

CHARCOAL iron tubes have for generations proven their qualities in heavy boiler service. Probably most of our readers use these tubes, but few understand the manner in which the iron is made—as indicated by the many requests for information on the subject. The following details of charcoal iron production methods as carried out by a well known manufacturer of the material will clear up some of the questions that have occurred to those using boiler tubes made from charcoal iron.

## USES FOR CHARCOAL IRON

Charcoal iron, made by painstaking hand-working in small forge fires of very limited output, is the purest of commercial wrought irons. Because pure iron is highly resistant to corrosion, charcoal iron has long been used in the manufacture of boiler tubes for locomotive, marine and stationary service.

In some quarters there is an impression that real charcoal iron is no longer obtainable. Metallurgical science and mechanical ingenuity, during the last half century, have evolved newer and cheaper methods of making certain kinds of iron and steel when tonnage output is of maximum importance, but there is yet to be developed another and better method of making charcoal iron, or an iron of equal purity.

While full advantage is taken of advanced laboratory knowledge making possible better metallurgical control, charcoal iron is made today exactly as it was 50 years ago. The little hearth fires have not changed, some of those at the plant from which this data was taken having been in continuous use nearly 50 years. Charcoal is still the fuel because it is practically free from sulphur. (Iron absorbs impurities and if coal or coke, though lower in price, were used as fuel, the iron would be unfit for boiler tube use.) Men, trained at the forge, work the glowing charge with long knobbling irons, just as their predecessors did.

# METHODS OF PRODUCING

Briefly, real charcoal iron can be produced from a charge of ore, pig iron, run-out metal, pieces of wrought iron, or pieces of steel, refined in a small forge fire of charcoal and worked by hand until the impurities are removed and the charge undergoes a complete change, becoming an almost perfectly pure, plastic iron.

For a better understanding of the charcoal iron making process, let us remember that charcoal iron is 99.86 percent pure, and that its manufacture is essentially a process of refining iron ore or any one of several ferrous metals to pure iron. Ore, which is high in certain impurities, can be re-

*Metallurgical engineer, Parkesburg Iron Company, Parkesburg, Pa.

duced to charcoal iron, but the refinement involves slow working and the use of considerable charcoal. White pig iron or run-out metal lower in impurities, can also be used as the charge and made into charcoal iron with less working. Or, the operation may start, further along the scale, with certain kinds of steel, from which most of the impurities have already been removed, so that the time required for the desired refining is still further reduced. In any event the finished product is the same, pure charcoal iron.

# IMPURITIES IN IRON REDUCED

The objectionable elements of carbon, manganese, sulphur, phosphorus and silicon, present in every form of iron and steel, are reduced to the merest trace in charcoal iron, their combined content being less than fourteen-one-hundredths of of 1 percent, as will be observed from the following analysis of a specimen of charcoal iron:

	Percent
Carbon	. 0.03
Manganese	
Sulphur	. 0.015
Phosphorus	. 0.03
Silicon	. 0.03

Fig. 1 .- Withdrawing Finished Charge

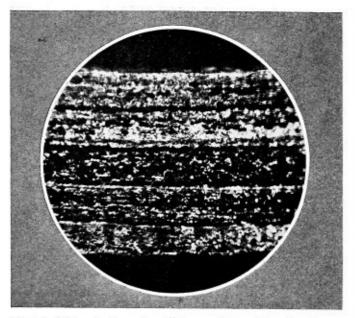

Fig. 2.-Microphotograph of Charcoal Iron Showing Layer Formation

The charcoal iron of primitive man was extracted from ores, refined probably in crude stone fireplaces on hillsides, the air to support combustion being supplied by natural draft through passages dug through the hill and facing the prevailing winds. The refinement of the ores containing many impurities was unquestionably a slow and inefficient process on account of the uncertainty of the blast and the lack of skill and knowledge of the artisans. Much charcoal and many hours were required to produce a lump of crude iron weighing less than 50 pounds.

## BLAST FURNACE UTILIZED

With the development of the blast furnace, the charcoal iron maker began to employ pig iron instead of the natural ore as his basic charge. There was no change, however, in the resulting product, which was charcoal iron. While some of the impurities had already been removed from the pig iron in the blast furnace, the average carbon content of the pig was about 3.50 percent, and required much charcoal and considerable time properly to effect the desired refinement.

While much of the impurities had been removed in the blast furnace, there were still present in the pig, considerable quantities of carbon, manganese, phosphorus and silicon which required much charcoal and considerable time to reduce.

# KNOBBLING TIME REDUCED

A further reduction in the knobbling time was secured by remelting the pig iron and running it out into flat, chilled plates, called run-out metal, which were then charged in the charcoal fire. The remelting having removed some of the impurities, less time was required for conversion, and the final product was real charcoal iron. Next, the advent of the puddling process of iron making released quantities of wrought iron scrap mixed with steel scrap which replaced the run-out metal as the charge.

About 1870, the development of the steel industry provided ideal material for charcoal iron manufacture. Certain kinds of light weight steel, low in carbon and other impurities, could be cut into pieces which were not only purer than the run-out metal or wrought scrap, but were much easier to handle.

Since the early '70 s steel has formed the charge from which charcoal iron has been made. The resulting product, its composition verified by chemical analysis, and its corrosive-resisting qualities demonstrated by actual service, differs not at all from charcoal iron made from ore, pig iron, run-out metal, wrought iron scrap.

When removed from the hearth-fire for further working under a steam hammer, the incandescent, slag-exuding lump is no longer steel, but an almost entirely pure plastic iron. The original charge has been changed from steel to iron, just as in the open hearth process a charge of scrap metal and pig iron undergoes physical and chemical changes which make it steel instead of iron.

## SUMMATION OF PROCESS

Summing up, briefly: The charcoal iron maker, starting with a small, 300-pound charge of the very best material the steel maker can supply, works it by hand in a fire of pure charcoal until impurities left by the steel maker are reduced to the merest trace and the charge undergoes a complete change in structure and composition, becoming pure charcoal iron.

Fig. 3.-Sixteen Thousand Bushels Like These are Used at the Plant Each Week in Making Charcoal Iron Boiler Tubes

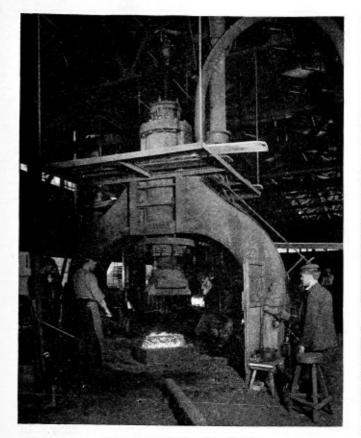

Fig. 4 .- Shingling the Bloom

Chemically the principal difference between ordinary low or a medium carbon steel and charcoal iron lies in the lower carbon and manganese content of the latter; basically, how-

Fig. 5.—Charcoal Iron Slabs Cut to Length and Piled for Heating

ever, the difference is due to the presence of slag distributed throughout the iron in filaments and thin plates which form protective barriers against corrosion of the iron.

# Administration of New Boiler Laws in Pennsylvania

PLANS have been practically completed to put into effect the boiler and elevator fee laws passed by the recent legislature.

The administration of these laws necessitates the inspection of boilers and elevators by qualified inspectors of the casualty companies and of the uninsured boilers and elevators by salaried employees of the department, who must qualify for these positions by passing a rigid examination test.

The credentials of all boiler and elevator inspectors issued prior to the passage of these laws have been recalled and new credentials will be issued to only qualified inspectors of the casualty companies and to other qualified inspectors who will become salaried members of this department.

#### CHARGE TO BE MADE FOR INSPECTIONS

It is expected that the fees received will meet the expenses incurred in the enforcement of the boiler act. All the owners of unused boilers shall pay a fee of ten dollars for each annual internal and external inspection of a boiler while not under pressure, which fee includes an external inspection of the said boiler under operating conditions, and the actual expenses incurred by the inspector while making the inspection. This includes the certificate fee of one dollar, which certificate is issued to all the owners of boilers, and which indicates thereon that the boiler is safe to operate at the pressure limit named in the inspector's report to the department of his examination of the boiler.

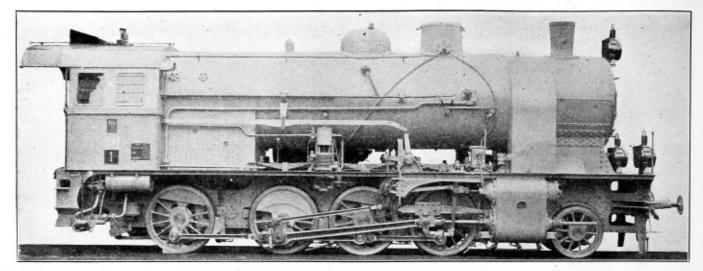

# Welded Joints in Unfired Pressure-Vessels

# (Continued from page 279)

longitudinal weld (and by this I mean a double-V weld) is not equivalent in strength to the average triple-riveted buttstrap joint; and under favorable conditions it may be permissible to allow it an equivalent efficiency, or approximately 85 percent. In making this statement I have reference to tanks which are constructed in accordance with A. S. M. E. requirements—provided these requirements are amended as was suggested at this meeting, so as to permit only double-V welded longitudinal joints.

In determining the insurability of welded vessels we place even greater reliance upon methods of construction than upon tests made after construction—such as hydrostatic and hammer tests. At the same time, there is no question but that the hydrostatic and hammer test will reveal some defective welds, and we believe that the test now prescribed by the Pressure Vessel Code should be retained. A hydrostatic pressure test of  $1\frac{1}{2}$  times the safe working pressure should be applied, and the vessel should be hammer tested while under this pressure. The hydrostatic pressure should then be raised to at least twice the safe working pressure, but not to the yield point of the metal.

[The foregoing does not imply, of course, that The Travelers is ready to insure any job of welding whatsoever. The weld must be made in the right way, and by a skilled workman operating with proper equipment; and when there is a good deal at stake, it may be necessary to investigate the shop conditions under which the weld was made.]

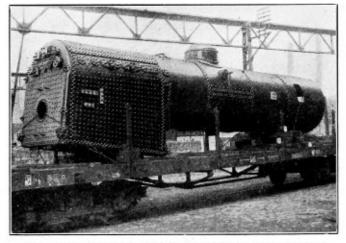

First Locomotive Built in Poland for the Polish State Railways

# Consolidation Locomotives Being Built in Poland for the State Railways

# By J. Dabrowski

THE new plant of the first Polish Locomotive Works at Chrzanow, Poland, has been completed and locomotives are now being delivered. The Polish Government placed an order with this company for the construction of 1,200 locomotives, deliveries to extend over a period of 10 years. The order included several types of locomotives for both freight and passenger train service. The first locomotives to be built are of the Consolidation or 2-8-0 type for handling freight traffic.

As the boiler shop of the locomotive works was not completed for operation as soon as the machine and erecting

Boiler for One of the Polish Consolidation Locomotives

shops, the boilers for these Consolidation type locomotives are being built by the oldest boiler construction plant in the country, W. Fitzner and K. Gamper, Sosnowice, Poland. The photograph of one of these boilers loaded for shipment shows them to be of a good modern type.

The 2-8-0 type locomotive is used extensively in Poland. An order for 150 locomotives of this type was given to the Baldwin Locomotive Works in 1920, and 25 additional locomotives of the same design were ordered subsequently. In the future, new locomotives will probably be built in Poland provided the capacity of the local plants is sufficient.

The new Polish locomotive illustrated is equipped with a Schmidt superheater and a Knorr feedwater heater. Westinghouse air brakes for drivers and train are also provided, the air brake now being applied to all new locomotives and cars, both passenger and freight. It has a greater cylinder horsepower, tractive effort and heating surface than the Baldwin locomotive, although the weight on the drivers differs but little. A comparison of the leading dimensions of the two designs is given in the accompanying table:

# The Determination of Chimney Sizes*

# By Alfred Cotton[†]

In this paper the author presents a simple and orderly system, based on accepted characteristics, for determining the sizes of chimneys. Under any specific conditions there is a definite static draft for a given height and a definite "maximum capacity" for any given diameter. Charts are provided which give the static draft and maximum capacity of chimneys up to 500 feet high and 25 feet diameter, from which the working draft and capacity are found by means of the fundamental curve. Other charts give factors for various atmospheric temperatures, for altitudes; and for approximate work based on boiler horsepower. A problem is worked out to facilitate an understanding of the system.

T is probable that no engineering subject is in such a chaotic state as that of chimneys. While much excellent work has been done and many formulas, tables and charts have been prepared, chimneys are nevertheless usually de-

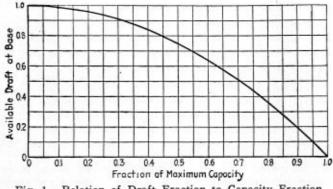

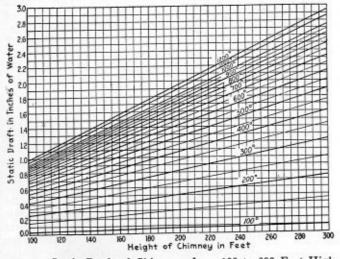

Fig. 1.-Relation of Draft Fraction to Capacity Fraction

signed by rule of thumb, and there are plenty of cases where their performance is either much greater or much less than was expected.

It is believed that the method of proportioning chimneys

outlined in what follows has the merit of giving definite sizes which are entirely free from conjecture, in a very simple and consistent manner.

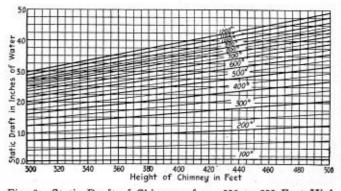

*Contributed by the Fuels Division and presented at the spring meeting, Montreal, Canada, of The American Society of Mechanical Engineers. Abridged. †Chief of research department, Heine Boiler Co., Mem. A. S. M. E.

# A DESCRIPTION OF THE METHOD EMPLOYED

It is convenient to consider the available draft at the chimney base as being the static draft less the draft lost by chimney friction and by acceleration of the gases, and this must equal or exceed the draft necessary to operate the boiler, etc.

The static draft is the vacuum prevailing under an imaginary condition when no gases are flowing. It is an absolutely definite quantity for any given circumstances and forms the starting point of this method.

The chimney friction varies as the square of the velocity of the gases. If the velocity is progressively increased, a point is reached where the chimney friction is equal to the static draft. This is the "maximum capacity," and it is

(Curves marked with mean temperature of gases in degrees F.)

just as absolute and definite a quantity for any given circumstances as is the static draft from which it is determined and it forms the end point of the method.

The draft loss due to chimney friction is in direct proportion to the height of the chimney. So also is the static draft. If we double the height of the chimney, we double both the static draft and the draft loss, and the maximum capacity is unaltered.

Since the chimney friction increases as the square of the velocity of the gases, the resulting curve is a parabola in all cases. This curve is presented in Fig. 1, and relates the load expressed as a fraction of the maximum capacity to the available draft expressed as a fraction of the static draft. This is a fundamental curve which applies to all chimneys at all temperatures of gases and of the atmosphere and at all altitudes.

#### STATIC DRAFT

Figs. 2 and 3 give the static draft for chimneys 100 to 500 feet high at sea level dealing with gases up to 1,200 degrees F. in temperature when the atmosphere is at 60 degrees.

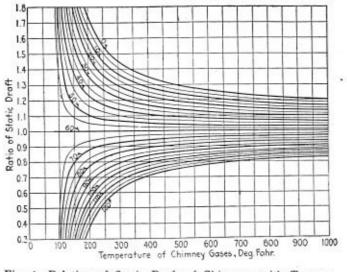

Fig. 4—Relation of Static Draft of Chimneys with Temperatures of Atmosphere from 0 to 120 Degrees F. to That at 60 Degrees F.

(Curves marked with temperature of atmosphere in degrees F.)

Another chart in the complete paper deals similarly with chimneys from 0 to 100 feet in height. Fig. 4 gives factors with which to multiply the static draft found from Figs. 2 and 3 to obtain the static draft for atmospheric temperatures other than 60 degrees.

## TEMPERATURE OF GASES IN CHIMNEY

The author's article on Loss of Heat in Brick Chimneys, published in *Power Plant Engineering*, Aug. 1, 1921, and which forms an appendix to the complete paper, includes some curves of temperature drop. These lead to the factors of Fig. 5, by which the mean temperature in the chimney may be found.

#### ALTITUDE AND STATIC DRAFT

The static draft at any barometric pressure B in inches of mercury is that at sea level multiplied by B/30. If the same load is to be carried at altitude as would be carried at sea level, then the same weight of gases must be dealt with. Since the density of the gases is less, their velocity must be higher, and the height of chimney necessary at altitude to provide sufficient draft to do the same work as at sea level, will be the sea-level height divided by  $(B/30)^2$ , or multiplied by its reciprocal which is given in Fig. 6.

Procedure (Masonry Chimneys):

- A = observed temperature of atmosphere
- $E \equiv$  observed temperature of gases entering chimney
- P = percentage appropriate to diameter and height as read from chart G = temperature of gases entering chimney above that of atmosphere = E - A
- $C = \operatorname{average}$  temperature of gases in chimney above that of atmosphere  $= G \, \times \, P$

 $C + A \equiv$  average temperature of gases in chimney.

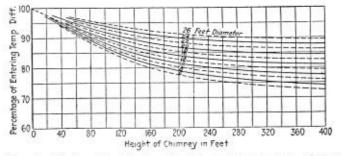

Fig. 5.—Factors for Finding the Mean Temperature of the Gases in Chimneys

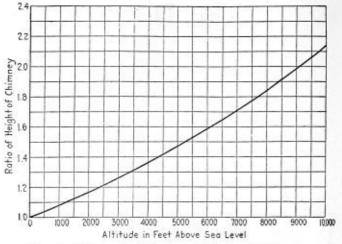

Fig. 6 .- Effect of Altitude on Height of Chimneys

#### MAXIMUM CAPACITY

Menzin, in his paper on Proportioning Chimneys on a Gas Basis, Trans. A.S.M.E., 1916, went so carefully over all the available data on chimney friction that the formula he presented has been used. Fig. 7 gives the maximum capacities of chimneys from 5 to 25 feet in diameter for various mean temperatures of gases with the atmosphere at 60 degrees at sea level. Other charts in the complete paper cover the range for diameters of from 0 to 10 feet. The maximum capacities as read from Fig. 7 are to be multiplied by the appropriate factor read from Fig. 8 when the atmospheric temperature is other than 60 degrees F.

It is convenient to assume that the velocity of the gases remains constant. Then the maximum capacity at altitude is that at sea level multiplied by B/30.

#### ACCELERATION OF GASES

The pressure difference required to accelerate the gases is conveniently stated as draft loss, and curves showing this draft loss at maximum capacity for each diameter have been drawn in Fig. 9, for different temperatures. Other charts in the complete paper covers the range for diameters of from 0 to 10 ft. The fraction of the draft loss for any desired fraction of the maximum capacity is the same for all maximum capacities. Fig. 10 gives this fraction.

The draft loss at sea level multiplied by B/30 gives the draft loss for altitudes.

#### AVAILABLE DRAFT

Enter Fig. 1, with the ratio of available draft to static draft, and read the fraction of maximum capacity. Divide the required weight of gases by this fraction and use the resulting maximum capacity to find the requisite diameter. Or with given diameter, read the maximum capacity and state the required capacity as a fraction of it. Divide the required draft by the fraction read from Fig. 1 and get the equivalent static draft. Add the draft required to accelerate the gases and read the height of chimney from Fig. 2 or Fig. 3. Several combinations of height and diameter can be found for any circumstances very quickly.

# DRAFT REQUIRED

The draft required at the base of the chimney is made up as follows:

1 Vacuum Over Fuel Bed. Fig. 11 shows the vacuum required in the furnace chamber for burning various fuels. The values are fair averages which accord with the author's experience with reasonably clean fires when hand firing and with average conditions of stoker operation. The brokenline curves were kindly supplied by Mr. Thomas A. Marsh,

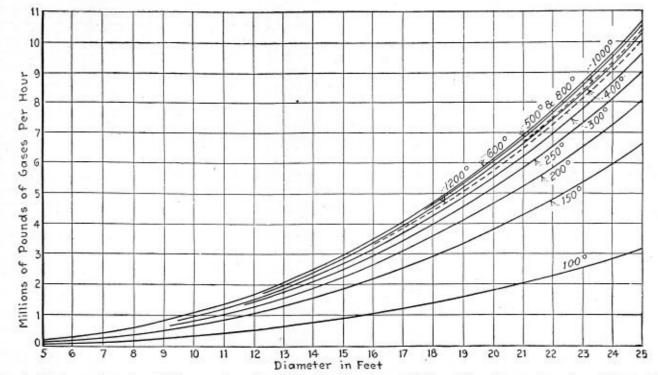

Fig. 7.—Maximum Capacity of Chimneys from 5 to 25 Feet in Diameter at Different Gas Temperatures from 100 to 1,200 Degrees F. at Sea Level with Atmosphere at 60 Degrees F.

Mem. A.S.M.E. With forced draft, a vacuum over the fire of about 0.1 in. should be maintained.

2 Draft Loss Through Boiler Setting. A curve should usually be obtained from the boiler manufacturer based on some proportion of excess air with the fuel to be used.

The draft loss through a horizontal, diagonally baffled, 14-high watertube boiler burning bituminous coal with 13 percent of  $CO_2$  in the flue gases is given in Fig. 12.

The effect of an alteration in the amount of excess air as indicated by the proportion of  $CO_2$  in the flue gases is shown approximately by the curves drawn in Fig. 13. Precise factors are not possible, but these are sufficiently accurate for the present purpose. The draft loss for any percentage of  $CO_2$  is to be multiplied by the appropriate factor to find the draft loss at some other percentage of  $CO_2$ .

3 Draft Loss Through Damper. Some may prefer to allow a little draft loss through the damper, the damper be-

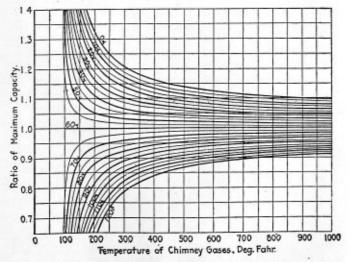

Fig. 8.—Relation of Maximum Capacity of Chimneys with Temperatures from 0 to 120 Degrees F. to That at 60 Degrees F.

ing not fully open, as a factor of safety. But this is quite unnecessary with the method of treatment being described. Of course, in some ill-designed plants there may be a real draft loss through the damper frame owing to its being too small, or through the damper's causing serious distortion of the stream lines when fully open.

4 Draft Loss Through Flues. The draft loss through flues is commonly taken as 0.1 in. of water for each 100 feet of length and 0.05 inch for each right-angle turn. This value results in the curves of gas weights and velocities of Figs. 14 and 15 for a temperature of 540 degrees and for rectangular flues whose sides have a ratio of 2:1. Other figures in the complete paper give factors for finding the weight and velocity at other temperatures for the same draft

(Curves marked with temperature of atmosphere in deg. fahr.)

2.0

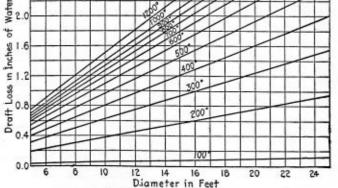

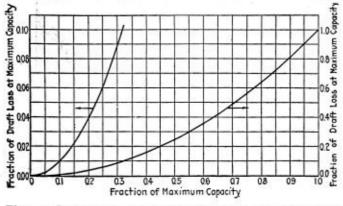

Fig. 9.—Draft Loss Due to Acceleration of Gases at Maximum Capacity of Chimneys from 5 to 25 Feet in Diameter with Temperatures of Gases from 100 to 1,200 Degrees F. at Sea Level

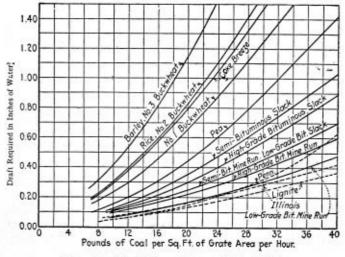

Fig. 11 .- Draft Loss Through Fuel Bed

loss, and the effect of the shape of the cross-section of the flue. A further development results in the curves of Fig. 16 which are based on the gas weights of Table 1.

The loss due to elbows is generally assumed as 0.05 in. for right-angle turns whose inside radius is not less than the width of the flue.

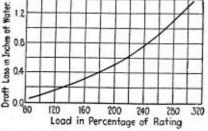

Fig. 12.—Draft Loss Through Diagonally Baffled Boiler 14 Tubes High with Superheater, Burning Bituminous Coal with 13 Percent of CO₂ in Flue Gases at Sea Level

The effect of different amounts of excess air on the draft loss in flues is the same as for the boiler setting as shown by Fig. 13.

TABLE I. WEIGHT OF FLUE GASES PER BOILER HO	RSEPOWER
Conditions	Pounds of gases per horsepower
Coal, natural draft Coal, forced draft Natural gas	90 60
Natural gas Oil Blast-furnace gas	60 45 100

# WEIGHT OF GASES

The weight of gases to be dealt with from any given fuel depends upon the proportion of excess air. It is convenient to calculate the weight of gases with different proportions of

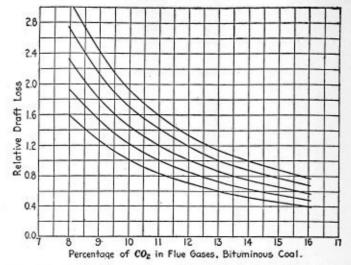

Fig. 13.-Relative Draft Loss through Boilers Burning Bituminous Coal with Varying Proportions of Excess Air

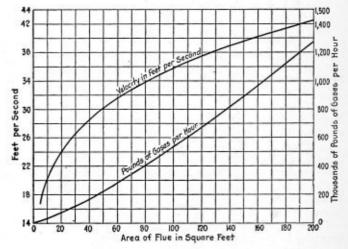

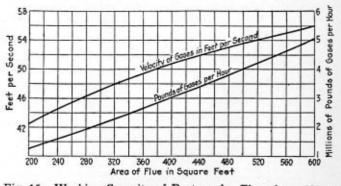

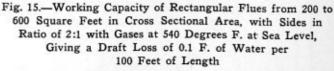

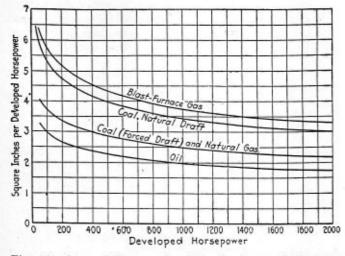

Fig. 14.—Working Capacity of Rectangular Flues from 0 to 200 Square Feet in Area of Cross Section, with Sides in Ratio of 2:1 with Gases at 540 Degrees F. at Sea Level, Giving a Draft Loss of 0.1 Inch of Water per 100 Feet of Length

excess air per pound of "combustible." Any percentage of refuse, including unburned coal going to the ashpit, can then be used to find the weight of gases per pound of dry coal or of coal "as fired." The efficiency of the boiler and furnace will determine the weight of coal per horsepower

or per unit weight of steam, and the weight of coal to be burned can then be found.

Chimneys for induced draft are computed in exactly the same manner as in other cases. Since it often happens that loads are increased later owing to the ease of doing so with induced draft, it is advisable to allow at least 0.2 inch of available draft at the fan discharge.

Fig. 17 is drawn for a working capacity of 30 percent of the maximum capacity. The natural-draft curve is computed at 90 pounds of gases per boiler horsepower, the forced-draft curve at 60 pounds, and the oil-burning curve at 45 pounds.

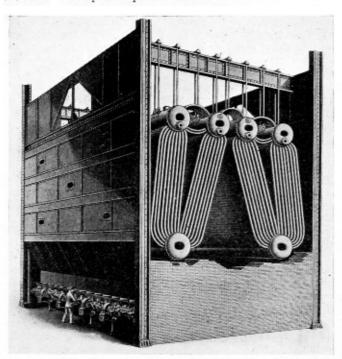

(To be continued in the November issue)

# Giant Boiler Contains Nearly Seven Miles of Tubes

A GIANT boiler of record-breaking size, said to be the largest boiler in the world, was recently installed in a Detroit plant (the Detroit-Edison Company). It contains 2,236 tubes of 3¼ inches diameter, having a total of 35,596 lineal feet, or about 634 miles. The distance measured from the street level to the boiler room floor is about 30 feet.

# MAIN PARTICULARS OF THE BOILER

This boiler has 29,820 square feet heating surface, and based on 10 square feet of heating surface per horsepower, it has 2,982 horsepower. It is equipped with 28 forced draft, multiple retort stokers, 14 at the front and 14 at the rear. The space requirements are 31 feet 8 inches width

Watertube Boiler Having 29,280 Square Feet Heating Surface

by 31 feet 0 inches depth by 47 feet 8 inches height. The weight of the boiler and the steel work for carrying it is about 500 tons. This mammoth piece of engineering consumes 420 tons of coal every 24 hours. The water evaporated is about 225,000 pounds every hour so that in actual size and performance it is entitled to the designation of "giant."

# Work of the A. S. M. E. Boiler Code Committee

T HE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the secretary of the committee to all of the members of the committee. The interpretation, in the form of a reply, is then prepared by the committee and passed upon at a regular meeting of the committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer.

Below are given the interpretations of the committee in Cases Nos. 391, 399 (reopened), 416, 419, 421 and 422, as formulated at the meeting of June 26, 1923, and approved by the council.

In accordance with the committee's practice, the names of inquirers have been omitted.

CASE No. 391—Inquiry: Permission is requested, under Par. 245, to operate watertube boilers with the tubes secured to malleable iron headers at pressures greater than 200 pounds per square inch. Also, attention is called to the fact that Par. 246b requires that the hydrostatic test be applied to all headers with tubes attached, whereas in certain cases it is not customary to attach the tubes until the boilers are erected in the field.

*Reply:* It has been proposed to revise the requirements of the Boiler Code in regard to the pressure allowance on watertube boilers when the tubes are secured in malleable iron headers, as follows:

"Par. 245-Change '200 pounds' in the third line to '350 pounds."

"Par. 246a—Add the following to this section: The malleable iron used for headers of watertube boilers shall conform to the specifications for malleable castings given in Pars. 111-120 (the paragraphs to be changed to conform with latest A.S.T.M. Specification).

"Par. 246b—Change '1,500 pounds' in the third line to '2,250 pounds.' Change the last sentence to read: A hydrostatic test applied to all new headers or elements with tubes attached shall be 500 pounds per square inch when cast iron headers or elements are used, and two and one-half times the working pressure when malleable iron is used, although the minimum test pressure with malleable iron headers or elements shall be 500 pounds per square inch."

CASE No. 399 (Reopened)—Inquiry: (a) Is any allowance permissible in the value of T in the formula in Par. 199 of the Code, for the combined thickness of the head and washer applied on the outside thereof under the nut of the through stay, when the washer is of large size and riveted to the head?

(b) Is the same increase in the value of T in the formula in Par. 199 applicable when a doubling plate is riveted on the inside of the segment of a head as if it were riveted on the outside of the segment?

Reply: It is the opinion of the committee:

That the Code does not stipulate whether the doubling plate shall be placed on the inside or outside; it is optional, but the inside plate of your design is preferable;

That the doubling plate must cover the entire segment and be riveted to the head in accordance with the requirements of the Code;

That 75 percent of the combined thickness of head and doubling plate shall be used in determining T;

That the value of C = 175 may be used for washers without doubling plate when stays are fitted with inside and outside nuts and outside washers, where the diameter of the washers is not less than 0.4p and the thickness not less than T;

That C = 175 may be increased by 15 percent when both washers and doubling plates are used, designed in accordance with the Code;

That the Code does not provide any additional value for C on account of the washers being riveted to the plate.

CASE No. 416—Inquiry: Information is requested as to the method of calculating, under the Rules in the Boiler Code, the required thickness of the bottom plate of the combustion chamber of a wet-back Scotch marine type of boiler when this bottom plate is curved upward or inward to the form of an arched surface between the points of attachment of the different furnaces and thus requires no staying.

Reply: It is the opinion of the committee:

That there is no rule in the Code exactly covering the construction submitted;

That the rule which has been followed from the General Rules and Regulations provided by the Board of Supervising Inspectors Steamboat-Inspection Service, Department of Commerce, is not applicable to the design submitted;

That the application of this rule to the case in hand does, however, provide a safe construction. Par. 239a of the A.S.M.E. Boiler Code may be used, which is equivalent to the Board of Supervising Inspectors' rule above quoted;

That a safer construction would be obtained if the arch curved plate were either stayed to the outer shell or reinforced;

That it would be better construction to build boilers with separate combustion chambers, with the bottoms so designed that they need not be stayed.

CASE No. 419 (In the hands of the committee)

CASE No. 421—Inquiry: Is it permissible to electrically weld a boiler shell, particularly the longitudinal joint, if sufficiently reinforced with bands as shown in the blue print, so that no stress is carried by the welded joint?

*Reply:* It is the opinion of the committee that a boiler so constructed would not meet the Rules in the Code unless the bands are made strong enough to withstand the full boiler pressure without giving any credit to the holding power of the welded shell, and unless some other method than the autogenous welding shown in the blue print is used for attaching the heads to the shell (see Par. 186 of the Code).

CASE NO. 422—Inquiry: Will it be acceptable, under the Rules of the A.S.M.E. Boiler Code, to use angle-iron attachments for the heads to the shell of cylindrical boilers, instead of the American practice of flanging the heads, and also to bolt the furnace front sheet and the rear tube plate to the boiler heads instead of riveting?

*Reply:* It is the opinion of the committee that provided the design is in accordance with the requirements of the Code as to material, stresses, construction, workmanship, inspection, and stamping, the boiler so constructed would meet the requirements of the Code.

# **Boiler Manhole Doors**

UITE a large number of explosions in marine boilers can be traced to defects in the fittings of manhole doors, and even when these explosions do not have fatal results, but result merely in the blowing of the contents of the boiler into the stokehold, the loss of time and money involved may be considerable. Such an explosion, happily unattended by fatal consequences, occurred recently to the boiler on a steam trawler (off the English coast) and from the official report of the inquiry into the causes of the explosion, held under the Boiler Explosion Acts, it appears that the explosion was entirely due to the blowing out of the joint between the flanged part of boiler-end plate and the manhole door. Following on the excessive clearance between the spigot of the door and the flange on the boiler plate excessive wastage had occurred, and the boiler was scheduled for repair at the conclusion of the voyage during which the explosion took place. It cannot be too frequently emphasized that at any point on a boiler where leakage of steam or of water occurs very rapid wasting of the metal parts is sure to follow, and any such leakage should, therefore, be promptly prevented. In the case of manhole doors, it is essential that the flange of the boiler plate should fit snugly into the manhole door preferably on both sides of the flange, but, if a grooved manhole door is not provided, at least on the inner surface of the flange, so as to provide support to the sides of the packing. Otherwise there is always the tendency for the packing to blow out with the consequences indicated above .- Shipbuilding and Shipping Record, London, England.

# Annual Fall Meeting of American Welding Society

# (Continued from page 276)

discussion will be centered on four important topics, namely, the interest shown in section meetings, the journal of the American Welding Society, ways and means of increasing membership and the general promotion of welding.

One of the principal sessions of the program is the industrial application session scheduled for Wednesday afternoon. All members realize that there are a large number of industries who are familiar with welding in a very vague way through infrequent newspaper accounts. It is their duty to call attention to the enormous possibilities of welding and the economies which result from its use. The Meetings and Papers Committee are preparing a comprehensive report on the industrial application of welding and the relation of the Society to the welding industry. There will be invited as guests representatives from all of the industries that should be interested in welding, living in Pittsburgh and its vicinity. Every member is requested to make a special effort to advertise this session and attend himself.

That steam users in both stationary and railroad practice, and to a lesser extent perhaps in marine practice, are looking towards the adoption of much higher steam pressures and temperatures as a means for effecting further power plant economies is evidenced by recent developments both in this country and abroad.

Early this year the Commonwealth Edison Company of Chicago ordered a boiler which is to supply steam at 1,200 pounds per square inch working pressure. Arrangements have also been made for the installation of a boiler working at the same pressure by the Edison Illuminating Company of Boston. In both cases the boilers were designed by the Babcock and Wilcox Company of New York.

Boilers delivering steam at from 800 to 1,000 pounds per square inch are in use in Sweden and Germany and pressures up to 1,500 pounds per square inch are being considered. In one case in England steam is to be generated at 3,200 pounds per square inch in an experimental plant.

From the foregoing it may be said that at the present time steam pressures up to 1,500 pounds per quare inch and temperatures up to 750 degrees are at least commercial and certainly indicative of a new field of development for the boiler manufacturer.

To meet the demand for the design and construction of boilers capable of supplying steam a t such high pressures and high degrees of superheat, both the boiler maker and the steel maker will have new problems to solve. In the case of the 1,200-pound pressure boilers mentioned above, for instance, the design calls for steam drums 48 inches in diameter with walls 4 inches thick made of forged steel, a problem quite different from that with which the average boiler maker is accustomed to deal. If such problems are to be successfully met by the boiler makers themselves, they must not only be progressive but also resourceful and competent to undertake responsibilities of a new order.

Fusion welding is gradually coming into its own as a safe, rapid and economical method of construction and repair in certain classes of boiler and tank work. The high pressure boiler is practically the only type of pressure vessel construction in which its use is prohibited.

In the section of this issue devoted to letters from our readers a short illustrated description of the largest all-welded steel boiler built in America is given which indicates in a measure the adaptability of the process to boiler work and the possibility of its use in boilers of higher pressure. The longitudinal seam construction with its unique method of reinforcement apparently insures an extremely safe boiler.

From the viewpoint of the insurance company, fusion welding is entirely acceptable in many classes of boiler and tank work as evidenced by the statements made by a representative of one of the most prominent insurance companies in the country at the recent welding conference held in New York to discuss the results of the welding investigation carried out by the Bureau of Standards in Washington. For nearly two years this company has insured welded pressure vessels of many kinds, working under high as well as low pressures—and with longitudinal as well as girth seams and heads fusion welded.

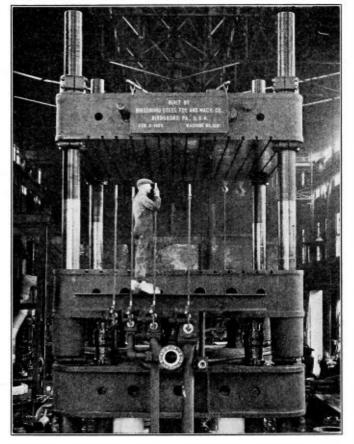

Up to this time this company when considering a pressure vessel for insurance has arbitrarily assumed a joint efficiency of 50 percent. In the light of the data made available by the Bureau of Standards, however, there would seem to be no objection for insurance purposes in allowing an efficiency as high as 85 percent for a double V longitudinal welded joint when the construction is carried out by competent operators and in accordance with A.S.M.E. requirements.

# Engineering Specialties for Boiler Making

New Tools, Machinery, Appliances and Supplies for the Boiler Shop and Improved Fittings for Boilers

Large Flanging Press for Boiler Shop

A FLANGING press, said to be the largest ever built, has recently been constructed for use in a railway shop. It uses an accumulator pressure of 1,500 pounds per sq. in., making a capacity of 1,200 tons. The machine is of the moving-up type, equipped with modern labor and power saving devices and safety appliances. A foundation pit, 8 feet wide, 25 feet long and 18 feet deep, is required as

1,200-Ton Hydraulic Press Built by the Birdsboro Steel Foundry & Machine Co.

the floor level in which the press is placed comes slightly below the face of the middle platen, which is the moving member.

The press, built by the Birdsboro Steel Foundry & Machine Company, Birdsboro, Pa., is of the four-column type, each column being 13 inches in diameter and 30 feet in length. The clearance between columns is 15 feet one way and 11 feet 11 inches the other way. The platens are 15 feet by 18 feet 3 inches, permitting the flanging of large steel plates. This construction makes available a flanging bed 15 feet by 15 feet. The top and moving platens are provided with a multiplicity of longitudinal T-slots to accommodate bolts for fastening dies.

The columns have long threads on the upper ends, thereby

providing an adjustment between the top and moving platens of from 12 feet maximum to 5 feet minimum. The inner nuts supporting the upper platen are made in halves, and the outer nuts are split on one side to permit the use of a wedge for slackening while they are being raised or lowered in adjusting the clearances.

Six ranges of power may be exerted by the press, which has three main cylinders and plungers 26 inches in diameter each with a lift of 6 feet. By admitting 1,500 pounds accumulator pressure to the center cylinder, only 400 tons will be exerted. When pressure is admitted to the other two 26 inch cylinders simultaneously, a pressure of 800 tons will be obtained, and by applying pressure to the three cylinders, 1,200 tons will be obtained.

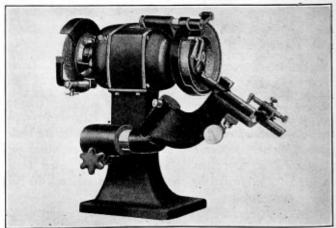

It is possible to exert three additional pressures by using the four jack rams in conjunction with either of the above three combinations. These rams are 9 inches in diameter and also are used for raising and controlling the motion of the moving platen while running up to the work and to perform light flanging.

An auxiliary cylinder is mounted on the center of the moving platen and moving therewith for stripping the work from the flanging dies. The hydraulic pressure is transmitted to this cylinder through a set of swivel joints. The press is of cast steel construction throughout, with the exception of the plungers, which are of chilled iron, ground and polished, and the tension bolts, which are of steel forged from metal cast ingots. The total weight of the press is over 300 tons.

# Bench-Type Twist Drill Grinder

THE bench-type twist drill grinder illustrated is an interesting new development of the Gallmeyer & Livingston Company, Grand Rapids, Mich., successor to the Grand Rapids Grinding Machine Company. The grinder is driven by a self-contained motor, enabling it to be placed in any position in the shop toolroom where most convenient.

In the basic principles of design and operation it conforms to other Grand Rapids twist drill grinders. It has a diamond truing device and the diamond is furnished as part

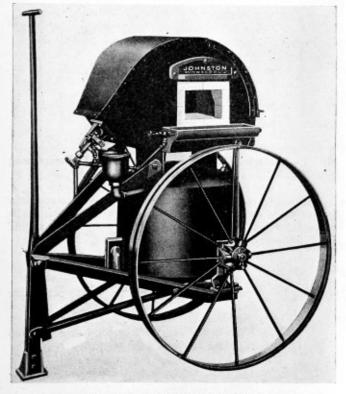

Bench Grinder for Twist Drills From No. 52 to 13/4 in.

of standard equipment for dressing the wheel. The holder is automatically placed in the right relationship with the grinding wheel so that it is close enough to grind the drills accurately and at the same time, the stop makes it impossible to bump the front of the holder into the grinding wheel. The machine illustrated is the A-7-T type with a capacity for drills from No. 52 to  $\frac{3}{4}$  inch. It is also made with a drill holder having a capacity of from  $\frac{1}{28}$  inch to  $\frac{1}{22}$  inch drills, in which case it is designated style B-7-T.

# Wheel-Portable Rivet Forges

A NEW line of oil-burning, wheel-portable rivet forges, designated as Nos. 1, 2 and 3, for use in boiler shops, car repair yards, and structural shops, respectively, has been placed on the market by the Johnston Mfg. Co., Minneapolis.

The general construction may be noted from the accompanying illustration. The frame is built on the "triangle" principle to permit of maximum rigidity, and the tongue is pivoted and acts as a guard for the burner. A large foot is provided to prevent sinking in soft ground. The wheels are 34 inches in diameter and 3 inches wide and are mounted in roller bear-

New Oil Burning Rivet Forge

ings. The forge is designed to burn fuel oil or any lighter oil. The automatic oil regulation provided is emphasized as maintaining a constant character of flame, eliminating scaling and smoking due to variable air pressure, and maintaining high combustion efficiency. The entire floor of the heating chamber is visible to the operator as he stands normally, without stooping.

The charging opening is 6 inches wide and 5 inches high and is said to maintain its shape and size for a long period, thereby saving oil and maintaining best operating conditions. An air curtain pipe is provided to deflect the hot gases upward. The forge is designed for relining with standard firebrick or special tile. The tank capacity is 20 gallons. The floor space occupied is 2 feet 9 inches by 3 feet 10 inches and the shipping weight is 825 pounds. In the Johnston non-clogging vacuum oil burner used, the oil supply is regulated indirectly by an air valve, which, it is said, cannot clog or vary, it being claimed that the burner operates continually without clogging or varying on oil containing so much free carbon and dirt that the usual burner will not maintain a fire without constant attention.

The burner has only two working parts, two needle point air valves, one of which regulates the compressed air and the other regulates the oil feed indirectly. The oil regulating air valve is plainly marked as shown, and is operated in the same way as other valves. High vacuum and large oil connections are provided in order that the burner may handle thick heavy oils. The oil feed increases and decreases automatically with the air pressure, and uniform flame is said to be maintained regardless of large variations of pressure in the air lines. The elimination of the necessity for readjustment of the oil feed, thus leaving the operator free to assist in other work, is a feature emphasized.

# BUSINESS NOTES

The Superheater Company is preparing plans for the erection of a 120 feet by 210 feet addition to its plant at East Chicago, Ind., to cost approximately \$75,000.

John Baker, of the mechanical department of the Chicago, Rock Island & Pacific, has been appointed vice-president of the Locomotive Firebox Company, with headquarters at Chicago.

The Prime Manufacturing Co., Milwaukee, Wis., contemplates the erection of a modern brass foundry of approximately 15,000 to 18,000 square feet. No definite plans have as yet been made.

S. G. Eastman, western sales manager of the Niles-Bement-Pond Company, with headquarters at San Francisco, Cal., has been transferred to Chicago, to succeed G. F. Mills, Chicago sales manager, retired.

The American Car & Foundry Company has purchased a tract of land 260 feet by 1,931 feet extending from the south branch of the Chicago river almost to Blue Island avenue and fronting on Wood street, Chicago, from the Edward Hines Lumber Company.

George F. Murphy, having completed the reorganization of the New York office of the Heine Boiler Company, St. Louis, Mo., has taken charge of the Philadelphia territory, with headquarters in the Pennsylvania Building, Philadelphia, Pa.; Harold P. Childs, formerly special representative of the executive offices of the General Electric Company, New York, has been appointed manager of the New York City office of the Heine Boiler Company, with headquarters at 11 Broadway; J. R. Fortune, formerly manager of the Detroit office, has assumed charge of the territories heretofore covered by the Pittsburgh, Cleveland and Detroit offices, with headquarters in the Dime Bank Building, Detroit, and in the Park Building, Pittsburgh. The Cleveland, Ohio, office has been discontinued.

W. E. Corrigan, of the sales department American Locomotive Company, has been appointed general sales representative of the company on the Pacific Coast with the title of district sales manager and headquarters in the recently established branch office, Rialto Building, San Francisco, Cal. Mr. Corrigan entered the service of the American Locomotive Company in 1909 and is a graduate of the four-yearcourse in locomotive construction which the company conducts in its engineering department in Schenectady. Since 1920, he has served for two years in the sales department at New York, as salesman for Alco accessories in the middle western territory and subsequently to the post on the Pacific Coast.

# Questions and Answers for Boiler Makers

Information for Those Who Design, Construct, Erect, Inspect and Repair Boilers—Practical Boiler Shop Problems

Conducted by C. B. Lindstrom

This department is open to subscribers of THE BOILER MAKER for the purpose of helping those who desire assistance on practical boiler shop problems. All questions should be definitely stated and clearly written in ink, or typewritten, on one side of the paper, and sketches furnished if necessary. Inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

# What is a Boiler Maker?

Q.-What is a boiler maker? How far does his knowledge and practice extend? A manager came to me and asked me to make a boiler to generate steam for a small engine he wanted to operate. He did not know the horse-power of the engine. How would I act in such a case or is it a boiler maker's job?-G. C.

A.—A master boiler maker is a master mechanic who should understand the principles of boiler design, construction, laying out and shop management. A boiler maker is a mechanic who can handle the various branches of the boiler maker's trade, such as fitting up, riveting, chipping and calking, tubing and staying, repairing and some laying out. Some boiler makers are all around mechanics and can handle equally well, all of these branches, others are specialists in one or more of them.

The question put up to you on the design of a boiler for an engine of an unknown size was not fair. The boiler maker is not expected to design boilers, as this comes under the head of mechanical engineering.

# Stay Calculations for Wrapper Sheets

Q.-Para as follows: -Paragraph 212-b of Part I, Section 1 of the A.S.M.E. Boiler code reads

"The maximum allowable working pressure for a stayed wrapper sheet of a locomotive type boiler shall be determined ..... by the method which follows ......

$$F = \frac{11,000 \text{ t X E}}{R - s \Sigma \sin \alpha}$$

in which:

in which:
\$\alpha\$ = angle any crown stay makes with vertical axis of boiler.
\$\sin \$\alpha\$ = summated value of sin \$\alpha\$ for all crown stays considered in one transverse plane and on one side of vertical axis of boiler.
\$s = transverse spacing of crown stays in crown sheet, inches.
\$\vec{H}\$ = minimum efficiency of wrapper sheet through joints or stay holes.
\$t\$ = thickness of wrapper sheet, inches.
\$P\$ = working pressure of boiler, pounds per square inch.
11,000 = allowable stress, pounds per square inch.
Will you kindly give me an illustration of the use of this formula in spacing stays for a locomotive firebox? I do not understand what is meant by the summated value of sin \$\alpha\$, \$-R\$, L, P.

A .- The solution given for the example illustrated in Fig. 1 covers the requirements of Par. 212, of the 1918 edition of the A. S. M. E. Code. The arrangement Fig. 1, for the stays is not in accordance with the requirements of firebox staying, but is indicated in this manner to illustrate the problem.

Consider the wrapper sheet to be 1/2 inch in thickness, and formed to a radius of 36 inches, 7/8-inch stays, spaced 7.07 inches apart each way. The angles the stays make with the vertical axis x-x are all shown.

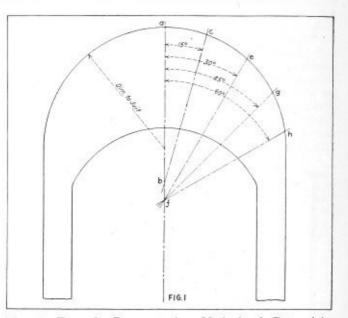

Fig. 1.-Example Demonstrating Method of Determining Stays for Wrapper Sheet

In Par. 212 (a) the first requirement given, is to ascertain the allowable working pressure between the stays, that is the net plate section, in accordance with Par. 180. The formula is as follows:

$$TS \times t \times E$$

$$R \times FS$$

in which TS = tensile strength of plate in pounds per square inch.

- t == minimum thickness of plate, inches.
- E = Efficiency of longitudinal joint or net section of plate between stay holes.
- R =inside radius of wrapper sheet.
- FS == factor of safety, equals 5 for new constructions.

The value of TS = 55,000 pounds per square inch.

-== 87.7 percent.

Substitute these values and those of the example, then  $55,000 \times \frac{1}{2} \times 0.877$ 

$$=$$
 133.9 pounds per square inch  
36  $\times$  5

maximum allowable working pressure without allowing for the holding power of the stays.

To this pressure is to be added the pressure obtained by the formula Par. 199, in which, use 70 for the value of C. The formula is as follows:

$$P = C \times \frac{t^2}{p^2}$$

t = thickness of plate in sixteenths.

p =maximum pitch between stays, inches.

The value of t = 8.

The value of p = 7.07 inches.

Substitute these values in the formula.

Then, 
$$P = 70 \frac{8 \times 8}{7.07 \times 7.07} = 89.6$$
 pounds nearly.

The pressure 89.6 is to be added to that, found for the net plate section, then in accordance with the first condition of Par. 212 (a). The allowable pressure equals 133.9 + 89.6 = 223.5 pounds per square inch.

For the second condition the pressure is based on the sum of the allowable pressure on the net plate section as already determined and that allowed on the stays.

The safe load allowed on a  $7_8$  inch stay using an allowable stress of 7,500 pounds per square inch, as given in Table 5, equals

 $0.7854 \times 0.875 \times 0.875 \times 7,500 = 4,509.75$  pounds. The area supported by the stay is,  $7.07 \times 7.07 = 49.9$ , say 50 square inches.

Then,  $4,509.75 \div 50 = 90.19$  pounds per square inch. 133.9  $\pm$  90.19 = 224.09 pounds per square inch allowable working pressure in accordance with the second condition.

The next requirement is to determine the pressure by the formula, in 212 (b),

$$P = \frac{11,000t \times E}{R - s^{\Sigma} \sin \alpha}$$

in which, P = allowable working pressure pounds per square inch.

= angle any crown stay makes with the vertical axis of the boiler.

- = summated value of sin for all crown stays considered in one transverse plane and on one side of the vertical axis of boiler.
- s == transverse spacing of crown stays in crown sheet inches.
- E == minimum efficiency of wrapper sheet through joints or stay holes.
- t = thickness of wrapper sheet, inches.
- R = radius of wrapper sheet, inches.

11,000 = allowable stress, pounds per square inch.

In the application of this formula ascertain the sin of the respective angles, *abc*, *afe*, *afg*, *afh*, and add them together.

Thus,	sin	15°	-	0.2588
	sin	30°	_	0.5000
	sin	45°	-	0.7071
	sin	60°	=	0.8660
				2.3319

The values to be substituted in the formula are as follows:  $t = \frac{1}{2}$ , E = 0.877, R = 36, S = 5, an assumed pitch for the crown stays, = 2.3319, sin  $15^{\circ} = 0.2558$ .

Then, 
$$P = \frac{11,000 \times \frac{1}{2} \times 0.877}{36 - 5 \times 2.3319} = 198$$
 pounds per

square inch.

The allowable pressure is the smallest value as found in accordance with the three methods given, and in this case is 198 pounds per square inch.

# Horizontal Return Tubular Boiler Design

Q.-We are contemplating building for stock some 10, 25, 50 and possibly 25 horsepower return tubular and vertical leg boilers, and we would be pleased if you could furnish us with diagrams and information on head bracing and flue spacing, together with a few cuts showing boiler head design for shell diameters 48 inch and up showing number of tube holes and size of same. Our desire is to manufacture standard boilers of a good design, and information that you might furnish us along these lines would assist us very much. Thanking you for any information you might send us in this connection, we heg to remain.-J. J. McL.

A .- The data you request cover a large amount of designing, typical constructions of both types of boilers that make

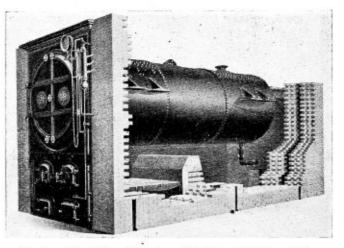

Fig. 1.-Flush Front Horizontal Return Tubular Boiler

it practically impossible to cover fully in these columns. We will endeavor, however, to give assistance that will show some of the features in the proportioning of horizontal return tubular boilers.

Boilers of this type are made in two types, the flush front and extended front types illustrated respectively in Figs. 1

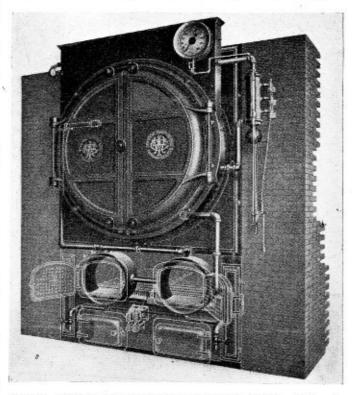

Fig. 2.-Extended Front Horizontal Return Tubular Boiler in Setting with Patented Firedoor Protector

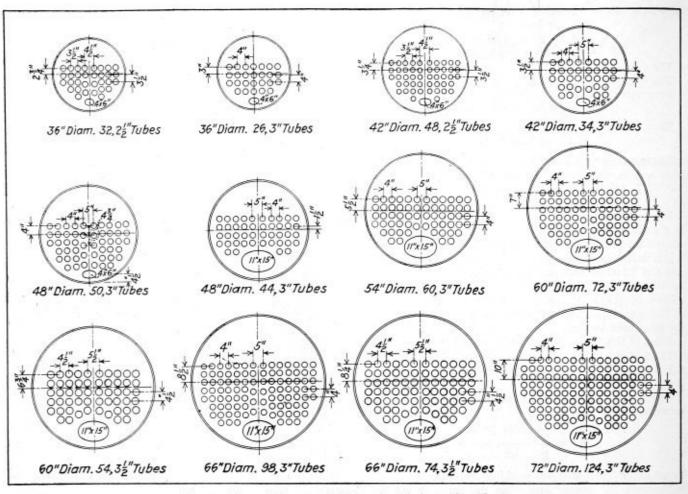

Fig. 3.-General Layout of Tubes for Various Size Heads

and 2. The terms "flush" and "extended" refer to the manner of setting the boilers.

The design of such boilers involves the use of the rules of the A.S.M.E. Boiler Code, now generally used in the United States. In the proportioning of a boiler for a given horsepower manufacturers have adopted 10 square feet of heating surface as required to develop a boiler horsepower. On this basis, calculations are made for the diameter of boiler, size of grate and other details as given for some of the details in Table I.

Fig. 3 shows a general layout of tubes for a number of standard size heads. The staying of the segments above and below the tubes should be made in accordance with the rules

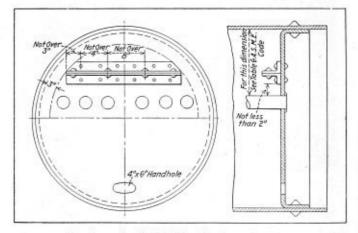

Fig. 4.—Showing A. S. M. E. Staying Requirements for Boiler Heads 30", 34" and 36" in Diameter

given in Par. 213 to 229 of the A.S.M.E. Code. For the smaller heads of 30, 34 and 36 inches in diameter the staying of the upper segment may be made as shown in Fig. 4, in which angles a or tee irons may be used.

For further information on the design of horizontal return tubular boilers and their layout refer to the book entitled "Laying Out for Boiler Makers" published by THE BOILER MAKER.

# Letters from Practical Boiler Makers

This Department Is Open to All Readers of the Magazine —All Letters Published Are Paid for at Regular Rates

# Largest Low Pressure Welded Boiler in the Country

O^N account of the increasingly large use of welding both by means of the oxy-acetylene and electric process for boiler repairs and construction, I enclose two illustrations of the largest all welded heating boiler recently built in the United States, together with details regarding the size, etc., in which no doubt the many readers of THE BOILER enviable record is one the manufacturers expect and hope to maintain. All boilers are being built to the requirements of the new A.S.M.E. Heating Boiler Code, besides being under the constant inspection and supervision of the Maryland Casualty Company inspector, who inspects and insures the entire production of this plant.

A description of the boiler illustrated is as follows: Built by General Boilers Co., Waukegan, Illinois, July, 1923, Catalog No. 229C—Serial No. 2098 Maryland Casualty Co., No. 1557—for Higginbotham Bailey Logan Company

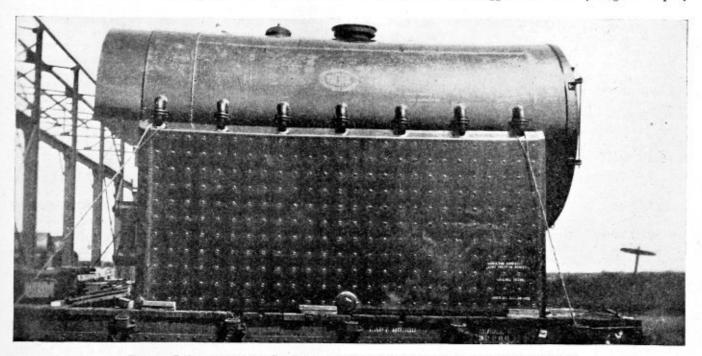

Fig. 1.-Boiler Claimed to Be Largest All Welded Low Pressure Boiler in America

MAKER and engineering profession in general will be interested.

This boiler was recently constructed by the General Boilers Company of Waukegan, Illinois, who manufacture the Pacific low pressure heating boiler exclusively, in all sizes, from the smallest, 22 inches in diameter for residences, up to and including those like the one illustrated, 84 inches in diameter and capable of handling a load of 35,000 square feet of steam radiation.

# GREAT DEMAND FOR THIS TYPE BOILER

That these boilers are giving satisfaction and proving more economical both from a construction and also an operation stand-point than the riveted or cast iron construction, is evidenced by the unusual demand during the past year for them from practically every state in the union and Alaska. From a safety stand-point these boilers are proving very satisfactory as the writer has kept personal records of nearly 2,000 of these electric welded boilers and as yet has not heard or known of an explosion or accident to any of them. This of Dallas, Texas—Total weight of boiler complete 30,000 pounds. Capacity of steam radiation 35,000 square feet, allowable working pressure 15 pounds. Shell, 84 inches in diameter, 14 feet  $6\frac{1}{2}$  inches long, 7/16 inch thick with  $\frac{1}{2}$  inch heads. Plates and heads being of Otis Steel Company 45,000 pound tensile strength flange quality steel.

It has 68-4 inch tubes 13 feet long, and 68-4 inch tubes, 11 feet 6 inches long of number 10 gage thickness, the tubes being rolled, and beaded on both ends in the usual manner.

# LONGITUDINAL SEAM REINFORCEMENT

The longitudinal seam being something out of the ordinary a description of same together with illustration Fig. 2 will probably make clear the construction of it. The shell plates were carefully planed and beveled and then butt welded, after which ribs 12 inches and 18 inches long, the same thickness of the shell plate, 7/16 inch, were cut to the inner curvature of the shell and bevelled on the curved edge. These ribs were then set edgewise on 6 inch centers across the shell seam and welded the full length on both sides of

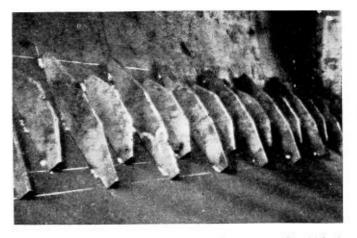

Fig. 2.-Longitudinal Butt Joint Reinforcements for 84-inch Boiler

the rib, to divide up the stress the ribs were used alternately, first an 18-inch rib then a 12-inch rib and then an 18inch and continued in this manner the full length of the seam, making a practically indestructible joint and considerably stronger than the original plate. The steam outlet on this boiler is 12 inches in diameter and 2-4 inch diameter safety valve outlets: All fittings to the shell are welded inside and out.

The firebox is constructed of 5/16 inch Illinois Steel Company 45,000 tensile strength plates flange quality steel, and is 95 inches wide,  $162\frac{1}{2}$  inches long, with staybolts  $6\frac{1}{2}$  inches by 7 inches pitch,  $\frac{7}{8}$  inch diameter, a solid smooth bolt being used, all bolt holes carefully countersunk nearly the thickness of the sheet before being welded.

#### TESTED FOR ONE HUNDRED POUNDS

The shell and also the firebox were carefully tested separately to 100 pound hydrostatic pressure showing no weakness or distress after which the shell and firebox were assembled as shown in view number one and again tested to 100 pound hydrostatic pressure with the same result.

All seams, staybolts, braces, fittings and connections were welded by the electric process using standard equipment and metallic electrodes; which process has been found after several years trial most satisfactory on this class of work. Waukegan, Ill.

J. H. PETHERICK, JR., Inspector.

# Don't Establish Precedents

THE slogan of one of the foremost financiers in New York City is "Never Establish a Precedent."

A number of years ago this seemed like a sort of foolish slogan to the writer, but as the years roll along I am beginning to agree with the financier. When something new comes along it may be necessary to establish a precedent but really new occurrences are exceedingly rare these days.

For example, if you are a specialist in your occupation, if you have spent a great many years making yourself efficient at it and know how to do things more economically than the other fellow, you surely have a right to charge for your knowledge and the person seeking knowledge should expect to pay in the same way that we all expect to pay for advice when we visit a doctor or a lawyer. Doctors and lawyers don't establish precedents by giving *free* advice the first call. They usually charge more for the first visit and less for succeeding visits.

I am inspired to write this because of the numerous mistakes I have made personally thereby not only weakening my own position but harming the business of other consultants. In one recent instance a stranger called and asked

for my opinion relating to a "small matter" involving power transmission. I advised him what to do and how to do it, and showed him where he could save \$300 by not doing what he intended to do.

A \$30 fee would have been only 10 percent of the \$300 and I would have been entitled to that much. Our conversation lasted only 15 minutes or so, that is true, but it took years for me to gather the knowledge and experience that enabled me to give him an answer so quickly and with such positiveness.

Did I charge \$30? I did not. The stranger asked, "Will there be a charge for this little talk?" with emphasis on the word "little," and his actions which were louder than his words indicated plainly that he was certain that there would be no charge. I chicken-heartedly said, "No. No. charge. You're welcome." The stranger thanked me cordially and walked out.

About a week later he came in again and wanted to "get a certain little thing straight," consuming another 10 or 15 minutes of my time.

I told him what he wanted to know to the best of my ability. He "thanked" me, as per the first performance, but on his way out I called to him and explained that I would have to make a small charge this time as I am in the consulting business to make a living and the only way in which I can make a living at it is to charge money for my services.

The fellow paid the \$5, but, do you know, he acted as though he was parting with an entire year's salary. I doubt if he will ever come again because he probably thinks that I gave him free advice the first time so that I could "sting" him the second time. Had I charged \$30 the first time I am certain that he would have respected me for it. He would have expected to pay the second time. The chances are that now he has very little respect, if any at all, and what is more he is probably going around telling his friends that I am a "grafter" and that if they want to get "stung" to go to Mr. Schaphorst.

Don't you think the financier is right? "Never establish a precedent."

Newark, N. J. W. F. SCHAPHORST.

# TRADE PUBLICATIONS

CO2 RECORDER ACCESSORIES .- Three devices, developed to prevent fouling and corrosion of CO2 equipment and the tubing which conveys the gas sample to the instrument continuously, are described and illustrated in an 8-page bulletin, No. 166-A, which has recently been issued by the Uehling Instrument Company, Paterson, N. J.

TOOL GRINDING MACHINES .- An instructive 20-page bulletin (No. 102) has recently been issued by the Greenfield Tap & Die Corporation, Greenfield, Mass. This bulletin describes the principal features, giving specifications and details, of the plain cutter and reamer and universal grinding machines made by the Greenfield Tap & Die Corporation. A complete list of the sizes, shapes and grades of grinding wheels is included in the bulletin.

LOCOMOTIVE AND OTHER CRANES .- The Industrial Works, Bay City, Mich., has issued an elaborate catalogue of its products commemorating the completion of a halfcentury of its existence. Sections are devoted to (1) locomotive cranes of rail, traction and crawling tractor types, and large, wharf and gantry cranes; (2) crane accessories, such as clam shell buckets, magnets and drag lines; (3) wrecking cranes ranging from 75 tons to 200 tons capacities; (4) special railway equipment, such as pillar and transfer cranes, portable rail saws and transfer tables; (5) pile drivers, pile hammers, etc., and (6) facilities for foreign service.

# SELECTED BOILER PATENTS

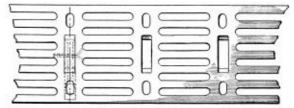

Compiled by GEORGE A. HUTCHINSON, Patent Attorney,

Washington Loan and Trust Building Washington, D. C.

Readers wishing copies of patent papers, or any further information regarding any patent described, should correspond with Mr. Hutchinson.

1,459,288. FIRE GRATE FOR LOCOMOTIVES. JAMES G. ELLIS, OF ST. LAMBERT, AND GEORGE WALTER MINGLE, OF MON-TREAL, QUEBEC, CANADA.

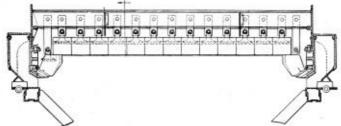

Claim 1.-A grate bar adapted to be shaken, provided with a plurality of spaced-apart identically formed holes extending therethrough from the top to

the bettom of the bar and tapering downward, said holes constituting draft openings and shaker arm receiving openings in combination with a shaker arm comprising a head portion fitting in one of said holes and a depending portion attached to said head portion and extending below the grate bar, said head portion being adapted to fit within any one of said holes. Eight claims.

1,463,240. SUSPENDED ARCH CONSTRUCTION FOR FURNACES. FRANK B. BIGELOW, OF DETROIT, MICHIGAN, ASSIGNOR TO MURPHY IRON WORKS, OF DETROIT, MICHIGAN, A CORPORA-TION OF MICHIGAN.

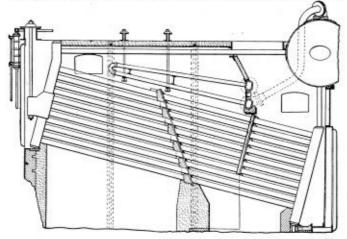

Claim .-- In an arch-construction of the character described, the combination of a plurality of arch-bricks, a main supporting-structure, a hollow supporting-member sidably mounted on said structure, a furnace front-plate apertured

in registration with said member, the latter being adapted to receive outer air through said front-plate aperture and deliver it into the space above the arch, a plurality of hangers supporting said bricks individually from said member, a back wall for the space above the arch apertured in register with said member and removable means normally closing said back wall aperture, the construction permitting the removal of any hanger and its injured brick by shifting the member longitudinally sufficiently through one of said apertures to free the hanger of the injured brick therefrom and temporarily supporting the remainder of the bricks not sustained by the member in its new position by a follower introduced through the other aperture.

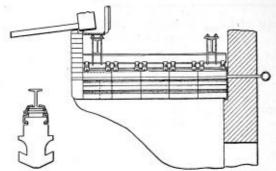

1,459,560. BAFFLE WALL FOR HORIZONTAL WATER-TUBE BOILERS, FREDERICK C. STIMMEL, OF CHATTANOOGA, TENNES-SEE, ASSIGNOR TO THE CASEY-HEDGES CO., A CORPORATION OF OHIO.

Claim 1.-A baffle wall, for horizontal water tube boilers, arranged transversely of the tubes and inclined forwardly for the purpose specified, said

wall being composed of interfitting tiles each having its front and rear faces inclined in a forward and upward direction, but at different angles, and the base of each tile being thicker than its upper edge. Twelve claims. 1,462,267. FURNACE ARCH. ROGER D. DE WOLF, OF ROCHES-TER, NEW YORK.

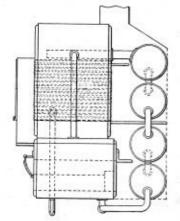

Claim 1.--A furnace arch comprising a plurality of supporting elements, a plurality of hanger bricks supported by each of said elements independently

of the other elements by means providing for the lowering and replacement of the bricks through the combustion chamber, and lining bricks carried by said hanger bricks to protect the latter and form a complete lining for said arch. Twenty claims.

1,462,763. STEAM BOILER. WAICHI NAKAGAWA, OF KITAKU, JAPAN.

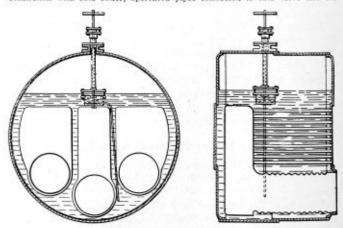

Claim 1.—A steam boiler comprising two lower cylindrical elements having each a furnace, an upper cylindrical element having a nest of fire tubes, a snoke box at the front end of the said elements interconnecting the space

between the three elements with the fire tube nest, a combustion chamber at the rear end of the said elements, a partition wall in the combustion chamber dividing it into an upper and a lower compartment in such a way that the lower compartment is in communication with the said space and the upper compartment with the rear end of the fire tube nest, drums in the two compartments interconnected in series and fluid connections between the end drums and the said elements respectively. Two claims.

1,464,225. BOILER PRIME PREVENTER. JOHN HENRY STOCK-HOLDER, OF NEW ORLEANS, LOUISIANA.

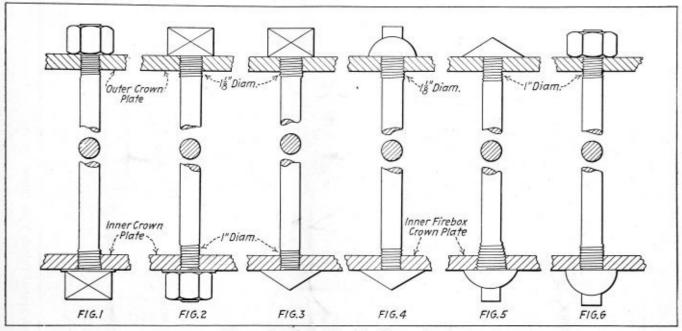

Claim.-The combination with a boiler having a feed pump in connection therewith for supplying the boiler with water, of a float controlled valve in connection with said boiler, apertured pipes connected to said valve and dis-

posed within the boiler, one of said pipes being disposed adjacent the water level, the other apertured pipe being disposed adjacent the bottom of the boiler, said float controlled valve forming means whereby the water within the boiler may be skimmed and the sediment in the bottom of the boiler removed, said float controlled valve being so constructed that when the water drops below normal level steam will pass through said valve to the feed pump for accelerating its action and when the water rises above normal level the valve will open a discharge pipe, thereby preventing priming of the boiler and at the same time admitting steam to the feed pump for feeding water to the boiler.

Types of Direct Stays for Crown Sheets

# Designing the Crown Sheets of Locomotive Boilers

Outline of British Methods of Staying Boilers Compared with American Practice

# By A. Wrench

Two types of crown stays are in use in Great Britain, namely, girder stays used with round topped outer covering plates, and direct stays used with Belpaire fireboxes. In America direct stays are used in conjunction with round topped outer firebox plates. Some years ago many locomotive engineers specified Belpaire fireboxes until at the present time many main line express locomotives are so fitted. It is claimed that the Belpaire form of construction gives a greater steam and water capacity where it is most required, and the use of the cumbersome yet flexible girder stays is dispensed with. The Belpaire form of construction introduces an additional flat surface, which is allowed to rise upward when the inner firebox first becomes heated.

# FEATURES OF THE GIRDER SYSTEM

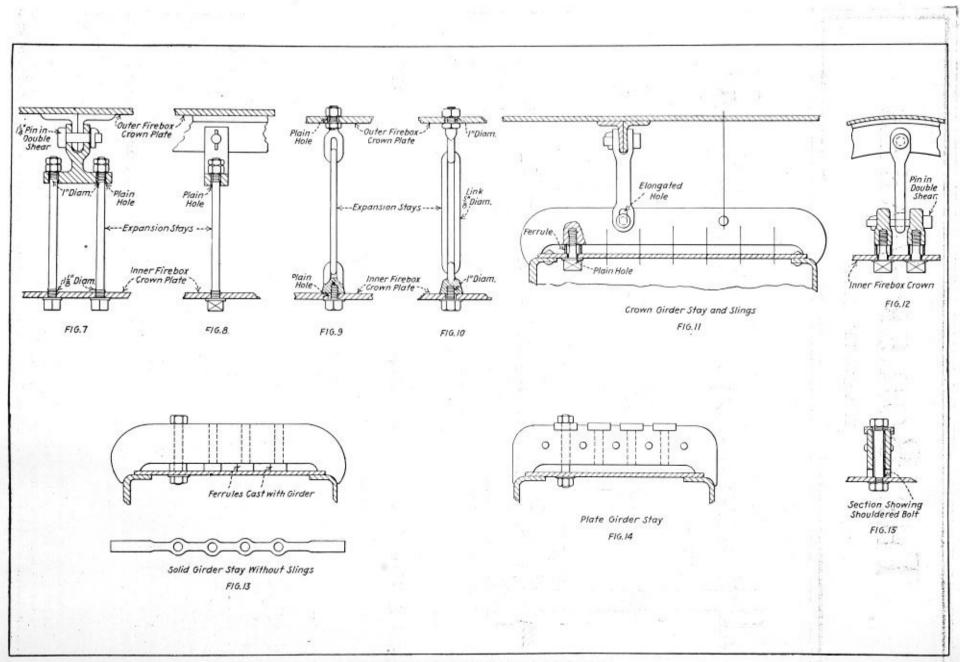

In the girder system the upward expansion of the inner firebox is accommodated by the girders being free to rise, the round top outer plate being rigid. To obtain a correct perspective of these movements one must follow the movements of a firebox from the time the fire is started when the boiler is cold until steam is raised. Directly the inner firebox becomes warm the plates and tubes expand and stresses occur in the plates and flanges.

The inner firebox, being rigid at the foundation, rises, and the outer firebox being still cold remains stationary. The outer crownplates of Belpaire fireboxes will be stressed during this period owing to the direct stays connecting the two crown plates, the stays being in compression and subject to bending stress. As steam is raised the outer firebox crown becomes heated and expands, and the pressure of steam bears on the two surfaces. This tends to equalize the stresses due to the first expansion and the strain on the stays becomes tensile.

The stress of expansion of the crown plate is greatest near the tubeplate and firedoor plate where the presence of the shell and riveted joint of the firedoor plate make these places rigid. It is usual for engineers to allow for this expansion by fitting three or four rows of expansion stays to allow these parts to rise.

# TYPES OF STAYS USED

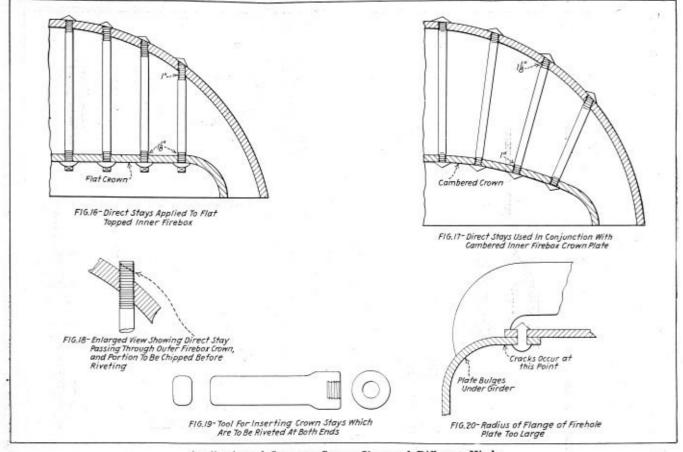

Two types of expansion stays are shown in Figs. 7-8 and 9-10. Sometimes cross girders are fitted at these parts, where

# Expansion Stays and Special British Type Stays

302

#### NOVEMBER, 1923

Application of Stays to Crown Sheets of Different Kinds

a . 11.

the radius of the side flanges will allow. In practice the free movement allowed by these expansion stays causes the saddle plate connecting the wrapper plate to the barrel to crack on the inside at the top as shown in Fig. 26.

When a boiler fitted with girder stays is subjected to strains of expansion during the period of steam raising, free movement of the inner firebox in an upward direction is allowed for, without the outer firebox crown, which is semi-circular being stressed. The downward thrust of the pressure of steam and the expansion of the outer crown bring the girders and slings into stress. The girders transmit the pressure to the end plates on which they rest. Any deflection of the girders is taken up by the sling stays connected to the outer crown by angles. These sling stays have an elongated hole at one end to allow the girders to rise. It is usual to fit the toes of the girders onto the tubeplate and firedoor plate flanges and it is necessary to make these flanges of small radius to enable the plates to take up the compressive stress, without distortion or cracking of the flanges.

Inner firebox crown plates of fireboxes fitted with girder stays are frequently found to be out of level. This generally occurs where the girders are secured together in pairs which allows the two outside girders to tilt when the firebox side plates expand. This distortion is avoided when all the girders are braced together. The flanges of the crown plate should be of ample radius to accommodate expansion or the plates will crack in this neighborhood after a short term of service.

# COMPARISON OF BELPAIRE AND WAGON TOP FIREBOXES

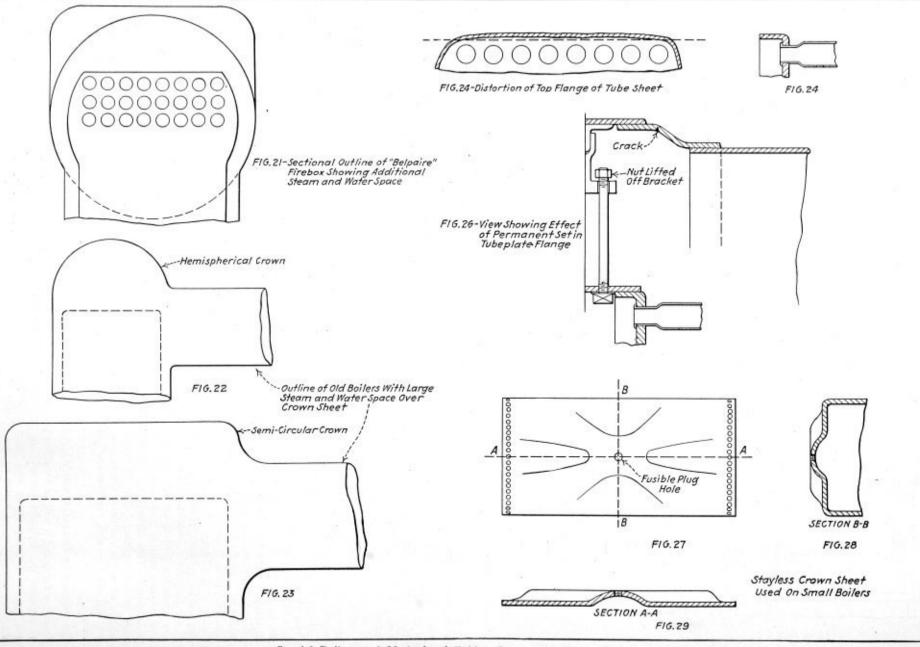

From the foregoing it will be seen that the principal differences between the Belpaire construction and the round or wagon top is: Greater steam and water capacity over the crown, free circulation of water by use of direct stays, absence of compressive stress on the firebox tube and firedoor plates, easy removal of sediment, utilization of flat outer crown to accommodate expansion and breathing of inner firebox. The principal advantage of the round topped firebox is the flexibility afforded by the girder stays and the semicircular construction of the outer crown plate which does not require staying.

It should be remembered that while the Belpaire firebox allows for a large steam and water space over the crown plate the volume of steam generated has to pass along a space which is a circular segment to get to the dome. Ample space for water and steam is found in old locomotive boilers without use of a flat outer crown, Figs. 22 and 23. It would appear to be inadvisable to use direct stays in conjunction with a round outer crown as the upward expansion of the inner plates would not be accommodated by any flexibility of the outer crown as in the case of the Belpaire. Also when using a flat inner crown plate direct stays will not be radial to the plates through which they pass.

#### AMERICAN PRACTICE

In America direct stays are frequently used for this type of firebox, but a cambered inner firebox is used to which the stays are radial. The surplus threads are chipped on the outside to enable them to be riveted correctly. Frequently in watertube boilers the generating tubes are not radial to the drums, and if these can be fitted effectively stays which are not radial to the plates can be used.

During the war the writer had to periodically inspect the boilers of 326 locomotives built by the Baldwin Locomotive Company and 98 locomotives built by the American Locomotive Company which were fitted with direct stays. No crown plate trouble was experienced on these boilers except when the boilers had been short of water, when, as a rule, several crown stays would leak which were easily put right by prossering.

Special Boilers and Methods of Taking Stresses in Crown Sheets

304

#### ALTERNATIVE METHODS OF CONSTRUCTION

If upward expansion must be allowed for in round topped fireboxes, some form of direct expansion stay can be used without resorting to Belpaire construction or girder stays. A cambered inner firebox crown is good practice as the efficient heating surface is increased, and in case of the boiler being short of water only a narrow strip of crown is uncovered before the fusible metal blows out of the plug. Repairs to crown plates are chiefly necessitated by fusible plug failures, accumulations of scale and oil on the crown, etc.; therefore, it is necessary to provide for accessibility of repair and cleaning. The heads of staybolts connecting the crown to girders should be on the firebox side and not in the water space so that they can be removed easily. Where direct stays are used the nuts should not be placed on the outside where they are only accessible by removing lagging.

Expansion stays in Belpaire fireboxes should be fitted so that the joints can be re-made if necessary from the firebox side. This can be done where stays as in Figs. 9 and 10 are used, but tubes have to be removed to repair stays similar to those shown in Figs. 7 and 8.

## DANGER FROM CLINKERS

The heads of crown staybolts are frequently made of large section to which clinkers adhere covering up much of the crown heating surface. The writer has recently removed some which weigh  $\frac{1}{2}$  pound and are  $4\frac{3}{8}$  inches long,  $2\frac{1}{4}$ inches wide. The whole covered up approximately 6 square feet of heating surface. Direct stays could be riveted on the firebox as this is the practice with side plate stays whether steel or copper. The heads would then lie flat against the crown and clinkers would not adhere. In case of leakage they could be calked. Several types of direct stays are shown in Figs. 1 to 6.

The solid girder is superior to the plate girder as it is cheaper to construct and allows the bolts connecting it to the crown to be easily renewed. Ferrules should not be separate from the girder but cast as a part of it. This method of construction facilities the removal and refitting of the girders whenever this is necessary to level the crown plate.

The dished or flanged crown shown in Fig. 27 is only suitable where small fireboxes of steel are used, such as those used in road rollers or small stationary boilers of the locomotive type. It will be noticed that the fusible plug is situated in the highest point which admits of only a small portion of the crown becoming bare before the attendant is warned of danger.

# BREAKAGE OF STAYBOLTS

Locomotive engineers differ in opinion as to the advisability of screwing crown staybolts into the inner firebox crown or using a plain hole. In case of a bolt breaking which is screwed into the crown no indication is given and the crown plate will bulge. On the other hand, a staybolt which is not screwed into the crown will blow out if broken and thus prevent further damage by indicating the failure. Crown staybolts usually break just above the crown where the threads commence and reference to Figs. 7, 9 and 11 will show what will happen in case of breakage in the respective cases.

Where girder stays are used the radius of the top firehole plate flange is usually made too large, which results in cracking and distortion at the points shown in Fig. 20. The side flanges of this plate should be large, but should be tapered off towards the top to enable the girders to effectively transmit the downward pressure on the vertical plate and not the flange. The same rule applies also to the tubeplate flanges, but these are usually made of small radius to allow the maximum number of tubes to be used. Frequently, too, top flanges of tubeplates are found to be out of true. This is caused by expanding flues and by the expansion stays allowing this part to rise during steam raising, resulting eventually in a permanent set. The nuts of the expansion stays under these conditions will be lifted off the brackets and will allow excessive breathing of the outer crown which will cause the plate to crack as indicated in Fig. 26. The flues will also leak, especially in the top rows. These nuts should be refitted to the brackets whenever the boiler is accessible internally.

While it is agreed that girder stays should be replaced by some form of expansion stays, boiler experts are reluctant to substitute a flat surface for a semi-circular one, and the writer's opinion is that the days of the round topped firebox are by no means over.

The following table shows the number of Belpaire and round top fireboxes in use on British railways, and will also show the difference of opinion among locomotive engineers regarding this important feature of locomotive firebox construction.

Railway	Great Western	Great Central	North Eastern	Lancashire & Yorkshire	Great Eastern	London & North Western
Engines fitted with Round top fireboxes	516	84	2,014	1,010	1,002	3,170
Engines fitted with Belpaire fireboxes	2,938	1,263	2	665	341	177

# Power Exposition to Be Held in New York

THE National Exposition of Power and Mechanical Engineering, to be held at the Grand Central Palace, New York, from Monday, December 3, through Saturday, December 8, is planned in cooperation with the national societies interested in the economy of fuel and in the production and use of power. The exposition will parallel the annual meeting of The American Society of Mechanical Engineers, which will be held at the Engineering Societies Building, 29 West 39th street, the first four days of the week. To avoid conflict between the two events, the sessions of interest to those who will attend the Power Exposition have been set for the mornings of the meeting, and the exposition will not open until one o'clock each day. The parallel arrangement will give engineers the desired opportunity to enjoy both events to the greatest possible degree.

The Power Test Codes Committee of the Society will hold a public hearing on the Code for Stationary Steam Generating Units and the Code for Locomotives. There will be an open meeting at which the report of the Fluid Meters Committee will be discussed. Progress in the program of society research and steam tables will also be treated at this meeting.

Further the A. S. M. E. Professional Divisions on Aeronautics, Machine Shop Practice, Management, Ordnance, and Forest Products will hold sessions of general interest to the engineering profession.

The Power Exposition offers a remarkable opportunity for the operating man to become acquainted with the latest devices in his field. This opportunity will be seized by the National Association of Stationary Engineers, the New York Building Owners and Managers Association, the New York Building Superintendents' Association, the Blue Room Engineering Society and the Ocean Associations of Marine Engineers who will attend the exposition in groups.

The monthly report to the President on the condition of railroad equipment sent in by the Interstate Commerce Commission shows that in September 5,262 locomotives were inspected by the Bureau of Locomotive Inspection, of which 47.6 per cent. were found defective, and 422 were ordered out of service. This percentage is less than for any month since July, 1922.

# Welding by Means of the Electric Arc Process

17 2 2 4 44

# A Comparison of the Costs of the Different Welding Processes as Applied to Railroad Shops

THIS report deals principally with the economic status of arc welding and is intended to assist members of this association in arriving at relative costs of electric arc welding and other processes, particularly that of oxyacetylene.

Welding operations; regardless of the process used, are merely applications of heat in proper form to the metals to be welded. The economics of welding, therefore, is largely, if not entirely, a matter of the economics of heat production and utilization. In the long run, the cost at which heat may be produced, suitable for welding operations, determines the process which costs the least to use; and, as long as economic laws apply to railroad shops, the process which will supersede all others is the one which gets the desired results at the lowest cost of producing the heat.

The issue today is, principally, between the heat produced by the oxy-acetylene flame and the heat produced by the electric arc. The field of forge welding is such as to eliminate the process from competition with the other two. Except for very heavy parts, Thermit welding involves an expense for its application, as well as for heat production, which, relative to the gas and electric welding processes, is so high as to practically eliminate it from the field in railroad shops.

The cost of producing heat depends, therefore, to a considerable extent, upon how directly the heat is produced. Fig. 1 shows graphically the steps which are intermediate between the production and utilization of the heat in a railroad shop. It is to be observed that the source of heat, whether the electric arc process or the gas process is used, is electric power. In the manufacture of oxygen, whether it be by the air reduction process or by the electrolytic process, electric power is the energy used to make the oxygen. This oxygen must then be compresesd in the tanks and the tanks transported to the store department. The store department delivers them to the manifold room, and the oxygen is delivered to the point at which it is used through a piping system. The manufacturer of the oxygen stands leakage up to the point at which the tanks are received by the store department. The leakage of the piping system, through which the oxygen is distributed to the points at which it is to be used, is paid by the railroad. Owing to the fact that oil cannot be used in the packing of the valves on the oxygen lines, the leakage of oxygen in the piping system amounts to a considerable figure.

The carbide, from which acetylene is made, is also a product of electric power. Carbide is made in an electric arc furnace. It must then be put in a metal container and transported to the user. It is then delivered to the acetylene generator room, where it is placed in the generator and combined with water to form acetylene gas. This gas is then delivered, through a piping system, to the point at which the heat is to be used.

The heat for electric arc welding is delivered direct from the power line to the arc welding machine, which merely converts the electrical energy into a form suitable for conversion by the electric arc into heat directly. It is obvious that the utilization of electric power for conversion directly into heat by the electric arc process involves a considerably less number of intermediate steps; and it could be assumed, without further investigation, that the cost of heat per B. T. U. is considerably less in the case of the electric arc process than the gas process.

Fig. 2 shows graphically the effectiveness with which the heat produced by the gas process and the electric arc process is used. In the former process, heat is produced in a neutral flame external to the metal to be heated. Due to the kinetic energy of the gases and their high temperature, a very large portion of the heat is carried off in hot gases and does no useful work. In the latter process, on the other hand, practically all of the heat is produced internal to the metals to be welded. Under normal circumstances, the largest amount of heat is produced in the heavier piece, and the balance of it is produced in the arc flame itself and the metal electrode. It is estimated that about 90 percent of the total amount of heat is produced either in the electrode or in the piece to be welded. There are no gases having kinetic energy -the heat losses are due to radiation and are relatively small.

Considering the cost of producing heat, without reference to the effectiveness of its use in the two processes, it is in-

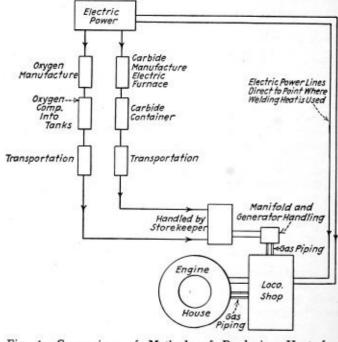

Fig. 1.—Comparison of Methods of Producing Heat for Welding

teresting to compare the cost of producing the amount of heat which is contained in the average pound of coal. Assuming that eleven thousand B.T.U. represents the average heat in a pound of coal, at \$5.00 per ton delivered to the railroad power plant; and figuring oxygen at 1¾ cents per cubic foot; generator acetylene at 8/10 of a cent per cubic foot; and electric power, which the railroad makes itself, at 1 cent per kilowatt hour, with an overall efficiency of 50 per cent for the arc welding machine; the relative costs of the three sources of heat are as follows:

1 lb. coal	11,000	B.T.U.	of	Heat,	1/4 cent
Oxy-acetylene	11,000		**		19.74 cents
	11,000		"		6.45 cents

^{*}Report read at the fourteenth annual convention of the Association of Railway Electrical Engineers, November 6 to 9, at Chicago, Ill.

Fig. 3 shows the thermal economy of the electric arc process and the gas process graphically. These figures show the relative cost to produce heat, as well as the effectiveness with which it is used. The data given on the cost per hour of operation of the two processes does not include any element of the relative amount of work possible to produce.

Fig. 4 shows, in parallel columns, at the center of the table, cost of production of the electric arc process and that of the equivalent size torch tips, which would be used in place of each size arc welding electrode. It is assumed that the gas process would use manifold oxygen, 50 pounds pressure, at the manifold and generator acetylene.

Exclusive of cutting, the welding operations done in railroad shops today, with either the gas or the electric processes, 85 percent may be done as well, or better, with the electric arc than can be done with the gas process. The 15 percent exception includes all brazing operations and a majority of the cast iron welding. On a number of large railway systems of the country, from 60 percent to 80 percent of the operations which may be performed by the electric arc process are being done in this way; and on many of the other large systems, the replacement of gas welding by electric welding has preceded 25 percent to 50 percent of the possible replacement.

It appears that oxy-acetylene for welding will go the way of acetylene lighting for automobiles and acetylene lighting for houses and buildings. The present widespread use of acetylene flame for welding is not due to any widespread preference for this process by those financially responsible

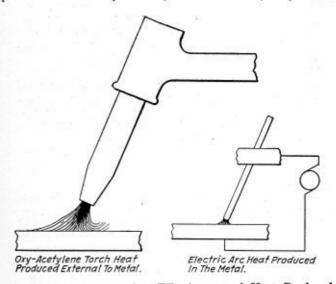

Fig. 2.—Diagram Showing Effectiveness of Heat Produced by Gas Flame and Electric Arc

for the operation of the railroads; but that the commercial use preceded that of arc welding is due rather, as in the case of automobile lighting, to the fact that these gases were already available, and that the initial development and installation cost necessary for its application was less than that of the electric arc. In view of the widespread movement to replace gas welding with electric welding, it is apparent that the time is rapidly approaching when the relatively small capital outlay will be made to eliminate the high operating expense of the gas welding process.

While it may be true that the actual application of welding does not generally come under the jurisdiction of the electrical men, they have, in the past, done much toward inciting interest, sufficient to result in at least initial purchases of arc welding equipment. As there is yet a great deal of work of this character to be done in the interest of arc welding, your committee feels that the electrical men can do much

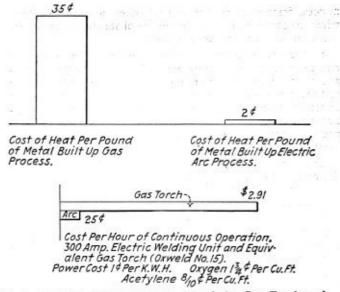

Fig. 3.-Relative Thermal Economies of the Gas Torch and the Electric Arc

towards the extension of arc welding by providing themselves with data on the economics of the process, proper equipment, and welding material necessary for the diversified applications of welding, and welding accessories.

In this connection, in order to eliminate any hazardous risk, incidental to arc welding, the use of the following safety precautions are recommended:

 It is very desirable that for use with portable welding generating sets, a combination of a safety switch and receptacle be used. This equipment should be so interlocked that the plug may not be removed without first opening the switch, and may not be inserted unless the switch is open.

It is, of course, desirable, as in the case of all safety switches, that the door be interlocked with the switch handle so that the door may not be opened with the switch closed.

 Portable cable used between motor and source of power should have an extra conductor inserted for use as a ground wire. For instance, with a three phase motor, a four conductor cable should be used.

The extra conductor should be plainly marked. It is recommended that this conductor be covered with a white braid for marking.

It is further recommended that this cable be covered with a flexible conduit, in which case the flexible conduit may be used to serve as a medium for grounding.

 Care should be exercised in the grounding of not only the frames of the motor and generator of welding sets, but also the covers and containing cases of switch and control

Size Rod Inches	Power K.W.H.	Arc Current Amp	Cost Per Hour	Cost Per Hour	Tip Size	Oxygen Cu. Ft.	Acetylene Gu. Ft.
18	4.5	120	\$.045	\$.53	6	19.2	23.7

1/2	30.0	400	.300				

Fig. 4.—Comparison of the Cost of Gas Welding With Electric Welding devices, frames of reactors and all other metal work which might become energized by the failure of insulation on cables, wires, or any part of the equipment.

4. The use of solder to fasten welding cables to ground clamps is not to be recommended. Due to the large currents and to the imperfect connection which is often obtained, resulting in heating of the ground clamp, solder is often partly or totally melted out of the lug. This results, very often, in imperfect operation and finally interrupts the operation entirely. Connection made with some form of clamping connector is more to be desired.

The committee desires to give thanks to Mr. Robert E. Kinkead, welding engineer, for his assistance in preparing the cost data of this report.

Committee: H. R. Pennington, chairman, supervisor of welding and electrical equipment, Chicago, Rock Island & Pacific Railroad; E. Hagensick, electrical engineer, Union Pacific Railroad; E. Lunn, electrical engineer, Pullman Company; E. S. M. Macnab, engineer of electric car lighting, Canadian Pacific Railway; G. T. Goddard, general electrical foreman, Illinois Central Railroad.

# **Reducing the Smoke Nuisance**

R ENEWED activities by civic authorities and organizations in the campaign to eliminate the smoke nuisance are reported by the United States Department of the Interior following a study of the problem of smoke abatement made by the Bureau of Mines. This campaign was suspended during the world war, when most of the smoke ordinances throughout the country were held in abeyance with the intent of allowing industries to operate unrestrictedly during the time when maximum production was necessary. With the return of normal conditions many cities have shown a determination to take up this matter seriously and work out a solution. Some 50 or 60 cities in the country already have smoke ordinances.

In domestic furnaces, it should be possible to reduce smoke from 50 to 75 percent without spending any money for additional equipment or without change in anything except the methods of handling the fuel. At industrial plants, smoke prevention is merely a matter of management, engineering judgment and designing skill. Any locomotive properly equipped with standardized smoke abatement devices can be made to do its required work without making dense smoke. All metallurgical operations can be conducted smokelessly with powdered coal, coke, fuel oil, or producer gas.

# HOW TO ELIMINATE SMOKE

Any operation requiring fuel can be conducted without objectionable smoke, and yet use bituminous coal in some form, states Osborn Monnett, consulting engineer of the Bureau of Mines, who conducted the investigation. If smoke abatement were merely an engineering problem it would present no difficulty. Experience has shown, however, that the problem is not so much an engineering as a psychological one. Until the public is thoroughly roused, demands smoke abatement, and shows continued interest in it, no permanent improvement is possible. Thus the part played by civic organizations and other bodies interested in bettering conditions is of high importance. Smoke abatement is not a matter that can be settled overnight and then left to take care of itself without attention, but is something that must be watched year in and year out if high standards are to be maintained.

The increase of the smoke nuisance in the United States has followed directly the progress of industrial development. When towns were small and a large proportion of the population lived in the country, the smoke nuisance was unknown. As people concentrated in the cities, there followed a tremendous increase in the utilization of power and heat and coal became the only feasible fuel where wood had largely sufficed before.

#### SOOT DEPOSITS RESPONSIBLE FOR NUISANCE

The deposit of soot on the heating surface of boilers and furnaces causes a serious economic loss by interfering with the efficient transmission of heat from the fire to the boiler or heater. In addition, the smoke that escapes into the atmosphere in smoke-ridden communities causes a considerable per capita loss to citizens through the damage to fabrics and merchandise, and also by the necessary extra cleaning and repairs.

Experiments conducted by the Bureau of Mines at Salt Lake City showed that a tremendous improvement can be made in the smoke performance of domestic furnaces if the firing is done with intelligent care. In the bureau's tests minimum smoke conditions were obtained when various types of boilers and furnaces were fired by what is known as the "coking method," by the "alternate method," and by the ordinary method of firing. One novel idea advanced is the starting of fires from the top, the coal being placed immediately upon the grate with a layer of paper just above the coal and with kindling on top of the paper.

Oil-burning systems offer another method of reducing residence smoke. Most of these systems are automatic.

Prepared fuels offer another possibility for reducing smoke. Of these, coke is probably the most feasible.

High-pressure plants that produce power for miscellaneous manufacturing establishments are the chief sources of industrial smoke. Most of these plants are hand-fired and consist of comparatively small units, approximately 150 horsepower each.

Stoker-fired plants have perhaps been most successful in smoke abatement. The boiler units are generally of large size, are equipped with mechanical stokers, and have been carefully designed by competent engineers. In addition, these plants are under constant supervision by skilled engineers, and firemen are always in attendance.

#### CUTTING DOWN LOCOMOTIVE SMOKE

Locomotive smoke has seemed most difficult to control, but many cities in the middle west have attempted to solve this problem with more encouraging results than were at first supposed to be possible. In the past ten years standardized equipment has been designed to reduce the discharge of smoke from locomotives. This equipment includes multiple-tipblowers, quick-opening blower valves, and induction tubes in the sides of the firebox to supply the air necessary for complete combustion. Such equipment is simple, is easily added by ordinary boiler makers, and has been discussed in detail in the proceedings of the various railway associations.

EXISTING LAWS SUFFICIENT TO CORRECT SMOKE EVIL

Success in smoke abatement depends largely on the administration of existing laws. Perhaps the most important consideration is the type of man for administering a smoke ordinance. It seems wise to have an engineer in charge who is familiar with boilers and furnaces and who can understand the engineering problems that will arise when the ordinance is put into effect.

The results of this investigation have been embodied in a report designed to make the various technical problems necessarily associated with the subject of smoke abatement thoroughly intelligible to the non-technical reader. Copies of this report, Technical Paper No. 273, may be obtained from the Department of the Interior, Bureau of Mines, Washington, D. C.

Schiess Machine Works at Düsseldorf, Germany

# Building Heavy Boiler Making Tools in Germany*

# Heavy Type Punching Machine and Upright Boiler Plate Bending Machine Among Products of Schiess Works

REPRESENTATIVE of the best in German heavy tool building, the machine tool works of Ernst Schiess, known as Ernst Schiess Werkzeugmaschinenfabrik Aktiengesellschaft, is located in Düsseldorf.

The company employs today about 2,000 men, or double the number of pre-war days. There is plenty of work in hand for export, but conditions on the Rhine are now affected by the French occupation of the Ruhr, and the future outlook for these shops, in common with other German industries of like character in the Düsseldorf district, is uncertain. Given a free hand, and there is little doubt that Schiess products would be finding an outlet across seas in as great proportion as before the war.

In the meantime alterations and changes are being carried on in the plant which could not be conducted during a period of large productivity. This will put the works in first-class shape to go ahead whenever the political situation clears up.

The firm produces practically all its own castings, and pieces up to 50 tons are readily cast. The principal tools built in the shops comprise heavy duty lathes, planers, boring, drilling, shaping and slotting machines, tools for boiler making, rolling mills, and for locomotive shops, wagon works and arsenal machinery.

Prior to the war Schiess operated a branch plant at Riga, but this establishment passed out with the war. Just now the noteworthy tools which the Düsseldorf plant is building are a reconstructed heavy duty double bed lathe designed for rapid work on turbine motors, crankshafts, gun and general forgings and marine shafting; a new tire boring mill for railroad trucks and the smaller size locomotive tires; a new profiling tool rest for railroad wheels; a "record" punching machine for curved and rectangular plates; a vertical bending press for use particularly in marine boiler work, and an automatic cutter disk grinding machine.

# MACHINE FOR ACCURATE PUNCHING

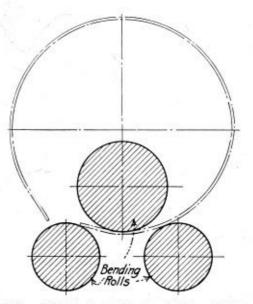

One of the heaviest outputs in numbers during the war, the "record" punching machine, was an important addition to ship construction work and heavy plate work. The Schiess machine will handle curved plates of any form, the machine punching with holes spaced at any regular or irregular pitches, without the necessity of employing formers or other devices. The gap punching and the multiple punching machines have held the field despite many drawbacks, to say nothing of the number of men required to handle them, the former machine largely because of the ability to punch how and where required, and the later machine because suited to deal with rectangular plates with uniform pitch of holes. The Schiess record machine punches throughout the working day 850 holes per hour. The work done is claimed to have accuracy greater than with other types, since in the case of the gap machine much depends not only on the plater, but on the remainder of the gang, whose combined efforts are required to move the plate from mark to mark:

The "record" punching machine comprises the punching machine proper, with operator seat, punches and dies cross traversing over a width of 7 feet 2 inches and the roller

^{*}Abstract of an article "Schiess Machine Tool Works of Düsseldorf" by "Captain Godfrey L. Carden, which appeared in *The Iron Age*, April 19, issue.

transporter, in two parts, for feeding the plates longitudinally under the punches. All features of the gun train are in evidence in this design. The roller transporter is actuated by an independent motor, while a second motor actuates the cross traverse of the operator and tools. The operator controls the motor from his seat, which is carried on the cross slide by a simple manipulation of levers similar to those on a Morse telegraph instrument.

The plate can be brought under the punches with the greatest exactitude and rapidity. This is done with celerity. The center finding attachment, which locates the point for

Usual Method of Bending Boiler Shell

punching, consists of two inclined projectors each carrying a small metallic filament lamp. These lights throw a sharply defined and brilliant + on the plate, the intersecting point of which is always exactly under the center of the punch, no matter whether the plates are flat or of varied thickness. This patent center finder is especially valuable when used on dark days or in gloomy shops.

Driving through gearing, an independent motor operates

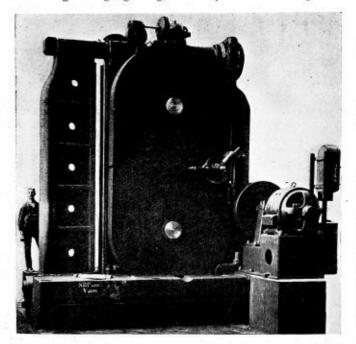

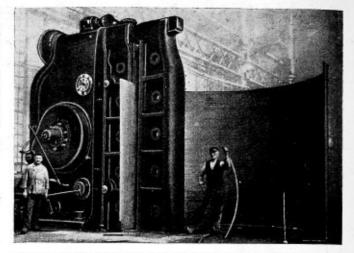

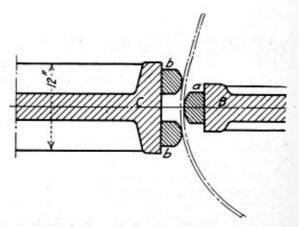

Plate Bending Machine for Boiler Work

Plates are Handled and Supported by Rollers Set Into Floor

the punching mechanism. A claw clutch which disengages after each stroke enables the punch to return automatically to its upper position. The dies are simultaneously lowered so that they are not blunted by the plate traversing over them. Punch and die holders are mounted to the extremity of a Ushaped frame, which is carried in long guides and of sufficient depth to clear the greatest width of plates. Die and die holder are lowered at the completion of each stroke. The punchings or burrs are automatically spilled into a receptacle

Method of Operation of Bending Machine. C is Girder Attached to Main Frame, B, Stationary Cross Arm, and b, b Two Cast Steel Tension Members

on the side of the machine. Lubrication of the punches is automatically effected at each stroke.

# UPRIGHT BOILER PLATE BENDING MACHINE

The upright boiler plate bending machine was designed to take care of certain disadvantages in the three-roller plate bending machine. One of these disadvantages consisted in the plate not being bent at all at its ends, due to the center distance of the bottom rolls, as shown in one diagram. Another disadvantage was the difficulty of checking the final shell diameter, as the distortion caused by its overhanging weight, especially with large diameter shells, is considerable. To overcome the latter disadvantage, bending machines with vertically arranged bending rolls were introduced, but this arrangement, it was found, could not compete with the higher efficiency and greater convenience of the boiler plate bending press.

Schiess has brought out a motor-drive press in contradistinction to the hydraulically operated press, which latter for years has been familiar in most shops. The hydraulically operated machines counted as difficulties leakage of pressure at the motor, and the necessity of avoiding tempera-

tures below freezing. The principle of the Schiess machine is seen in a second diagram. The accompanying photographs show front and rear views of the machine. From the diagram and the other illustrations it will be seen that there are a powerful main frame a of cast iron, and two tension members b of forged steel, which serve to hold in place the strongly constructed stationary cross-beam B of cast steel. Reciprocating and arranged between A and B is the strongly ribbed girder C, also made of cast steel.

Passage of the shell plate through the machine is progressive and automatic. To reduce friction, the plate is carried along on roller bearings arranged on either side at the base of the machine. On its top side the machine carries the motor and gearing actuating the top tension member, which, for the purpose of lifting out the finished plate cylinder, is turned into a vertical position. Details of three sizes of this machine are carried in the table.

Among the advantages of the machine are claimed to be greater number of strokes per minute and therefore greater production, no leaking of pistons or valves, no freezing of hydraulic pipes, and that it is always ready for use whenever required.

# Safety Problems of High Pressure Vessels*

Unfired Pressure Vessels Used in the Chemical Industry Offer a Broad Field for Development

# By Samuel S. Caskey[†]

THE subject, high pressure vessels, as understood in this discussion, deals with those vessels employed in chemical and similar processes other than steam vessels, such as boilers, steam accumulators, digesters, air pressure tanks, hydraulic apparatus, etc., for which laws have already been laid down and formulæ for designing have already been authorized and compiled by many states; the American Society of Mechanical Engineers and other engineering societies. They are variously called in the trades, autoclaves, converters, reactionary kettles, thionators, chloronators, carbonization kettles, dissolving kettles, fusion kettles, jacketed nitrators, sulphurating kettles, etc. The typical vessel I have selected is the autoclave, or closed, high pressure, high temperature, agitation vessel, carrying pressures from 60 to 1,500 pounds and temperatures from 212 degrees to 600 degrees F.

Eight or ten years ago most of the designs followed England and Germany, but since then they have been redesigned and built more according to American ideas. In the same time there have been built in this country about 200 different types, of which I have designed 70 or more types for the company with which I am associated. In fact during that time the advance in high pressures and high temperatures has been very marked, and it is hard to tell how rapid the demands on our ability to design and our knowledge of materials will be.

## HIGHER PRESSURES USED

We are at present reaching pressures double this and temperatures approaching the critical temperature. The distinguishing feature of all these vessels is the combination of such advanced pressures and temperatures which set up complicated and terrific strains and I wish to tell you some of the troubles we have had in our experience in designing for

*From a paper read at the annual meeting of the National Safety Council, Buffalo, N. Y., October 3.

†Engineering department, E. I. Du Pont de Nemours & Company, Wilmington, Del. efficiency and safety. You will appreciate these troubles when you learn some of the requirements of the processes that have to be considered.

The higher pressure vessels are nearly all closed fusion reactionary vessels and seldom have there been two of the same design, some detail always varying for a special reason. Heating and cooling in these vessels is nearly always very rapid to save time in the process yet some of the processes last three to four days. One instance of terrific grief to any kind of vessel is the case we have of a reaction kettle in which at a critical point in the process and when the materials are at red heat, water is introduced to produce pressure within the vessel for decanting a very quick setting material. Imagine the expansion and contraction strains under this treatment; the control depends entirely on the operators watching the steam gage. In many cases the reactions get beyond control and safety valves must be relied on. In other cases it is hard to get the proper heat arrangements so that there may be uniformity of heating.

Some vessels requiring low temperatures may be heated by steam jacketing. High temperature vessels must be heated by oil jacketing and vessels requiring still higher temperature may be fired directly with gas or oil, and we have still other types that must be heated to the critical pressure and critical temperature, which means that this combination of pressure and temperature is the point at which water and steam have the same properties, that is, the same weight per cubic foot and the same heat content. Another way of putting it, is, we have come to the end of our steam tables as they are used today and modern authorities differ as to their exact value. You will see that we have already arrived at a mechanical and manufacturing stage which had its inception over fifty years ago and had to do with the realm of thermodynamics. In fact we are beginning to work with a condition that is very unstable and beyond which little or nothing positive is known as vet.

At this writing we have news from England of a steam

temperature.

### PROBLEMS MET IN CONSTRUCTION

Our first task and first considerations were metallurgical, that is, whether the vessels should be made of cast iron, steel, or welded steel, and what quality of welding should be used.

Most European designers carried extreme fiber strains which were too high for this class of manufacture, because there is a safety factor for expansion and contraction required beyond anything allowed in the past. Seldom, if ever, do we allow strains greater than 6,000 pounds in cast steel, 1,500 to 2,000 pounds in cast iron. Autogenously welded vessels are permitted to carry 8,000 pounds extreme fiber strain, but electric or acetylene work should not be used except for very moderate pressure in welding pressurevessels because of the human element entering into the welding operation, and the greater susceptibility to corrosion of the weld.

Our second problem was to design a vessel of such shape as could economically handle the quantity of material which was to be worked and of such shape that the greatest strength and adaptability would aid in the fabrication of the vessel.

In all of these different types and combinations of temperatures and pressures, we have had the difficulty of supplying proper safety valves or relief mechanisms.

We have already designed two types of safety valves, neither of which has been entirely successful and it is our problem to go further with this item.

## DETAILS OF VESSEL

The general outline of the vessel in mind is a flanged cylinder with a spherical bottom, closed with a lid also spherical and flanged, with the drive mechanism, manholes, thermometer wells, sampling entrances that are to be accommodated and superimposed. The most difficult problem is that of making the joint between the lid and body. The material of the joints must first withstand the chemical action of the charge. It must also be tough enough to resist the pressure on the joint. The ordinary fabric and composition materials fail very often and quite often we must introduce grooves and metallic gaskets, but we are not yet able to consider this matter solved.

The fact that all drives, manholes, thermometer wells and sampling entrances must be accommodated on the lid and all joints packed makes the problem one of machine design.

Another trouble, subject for consideration, is the agitator which at present has no system of design whatever. The energy consumed by a badly designed agitator is very great, and I might say the efficiency and the yield of any process of necessity depend on whether an agitator does the proper work or not.

### DESIGN OF BOLTS FOR PRESSURE VESSELS

Our experience has taught us that in designing bolts for the head, care should be taken not to have these bolts too powerful, for the reason that in erecting the autoclave they might be pulled so tight as to strain the flanges and thereby make the joints conical. Once this happens, it is almost impossible to recover tightness.

We have learned also that when open slot holes are used in the upper flange of the vessel, they positively must be round and not square at the bottom of the slot, because in casting, shrinkage strains develop at sharp corners, and in bolting, they will gradually fatigue under repeated tightening of the bolts and rupture. In casting a vessel, it is necessary to cast it with the flange up so that the bottom will be of clean material without blow-holes, sand-holes or cold shots, therefore, such material should be run as a header to the flange metal to make a homogeneous and perfect flange. This same applies to the lid. We have been compelled to give up cast-

plant using 3,200 pounds pressure and 706 degrees F. ing vessels of so-called semi-steel, except in very small dimensions, for it is impossible in a large casting to keep the steel from segregating at the bottom while cooling in the mold. It invariably results in a distinct line of separation between the cast iron and the steel, and particularly in direct firing, will result in the expansion and contraction taking place in this particular line and nearly always breaking away causing damage and danger.

## FREQUENT INSPECTIONS MADE

Considering the increased requirements over usual custom and, after a discussion with all those concerned, we ordered to be followed out a definite plan of periodic inspection and report to detect weakness and forestall accident. Following out these orders, an inspector versed in this work and with proper mechanical education, was appointed to make the first inspection. For his aid, I prepared two questionnaires, one for data to be collected, and one on which to report inspection facts. All vessels were fitted with thermo-couples and potentiometers for observation and control during operations. Test data of manufacturer was stamped when possible and posters of the last inspection were attached to create confidence and establish morale. We have followed, and are still following up these inspections.

#### DETAILS OF PRESSURE TEST

Hydrostatic test applied
Date new safety disc was insertedJuly 10, 1923-Tagger's tin010 thick, 2 & inch. dia.
Condition of bolts and studsGood. External condition of shellNot examined.

Up to the present time, a total of 60 pieces of apparatus has been inspected and tested. In most cases, leaks were discovered at gaskets and fittings. Wherever it was possible to stop these leaks by the tightening of bolts or making slight adjustments, this was done. Where we found it impossible to overcome them, however, except by inserting new gaskets or making repairs, a record has been made on our inspection data sheets.

In general, vacuum apparatus shows more pronounced leaks than pressure vessels. This is to be expected, since leaks of this nature are not self-evident, but are only found by test.

# The Determination of Chimney Sizes—II*

# Charts and Examples Showing a Logical Method of Designing Stacks and Checking Performance

# By Alfred Cotton[†]

IG. 10 shows that at 0.3 of maximum capacity the draft loss due to acceleration of gases is 0.09 of that at maximum capacity, or, say 0.10 for use in this approximate

way. Fig. 1 shows that the available draft at 0.3 of maximum capacity is 0.91 of the static draft. Therefore the draft required at the chimney base divided by 0.9, for this approximate work, and added to the draft loss due to acceleration of gases gives the required static draft. The necessary height of chimney can then be directly read from Fig. 2 or Fig. 3 after making due allowance for temperature drop with the aid of Fig. 5.

The accuracy of the results depends only upon that of the constants. For all ordinary cases only a few of the charts are used, and it is an exceedingly simple matter to solve any problem.

A central power station is to have groups of four 1,400 horsepower boilers to each chimney. The boilers are to be 14 tubes high and are to carry peak loads of 300 percent

*Continued from page 289 of the October issue. From a paper pre-sented at the spring meeting, Montreal, Canada, of the American Society of Mechanical Engineers, Abridged. †Chief of research department, fleine Boiler Company, mem. A. S. M. E.

of rating when the exit gases will be at 640 degrees. Forgeddraft stokers are to burn bituminous coal of known analysis with 30 percent of excess air.

An approximate idea of the chimney is first arrived at. The total horsepower to be handled is 16,800, for which a diameter of 16 feet is read from Fig. 17.

The draft required at the base of the chimney is found to be 1.55 inches made up of 1.3 inches draft loss through boiler (from Fig. 12), 0.15 inch draft loss through the flues, and 0.1 inch vacuum over the fire. Dividing this by 0.9 gives 1.72 inches as equivalent static draft, to which is added an assumed 0.1 inch for acceleration of gases, making a total static draft of 1.82 inches. Assuming a mean temperature of chimney gases of 550 degrees, a height of 270 feet is found from Fig. 2.

The combustion data for the coal are worked out and the total weight of gases per pound of combustible found. Using the predicted boiler and furnace efficiency, the weight of combustible per hour is found and then the weight of gases per hour. Tabulation of data is then commenced as in Table 2, using a number of diameters above and below

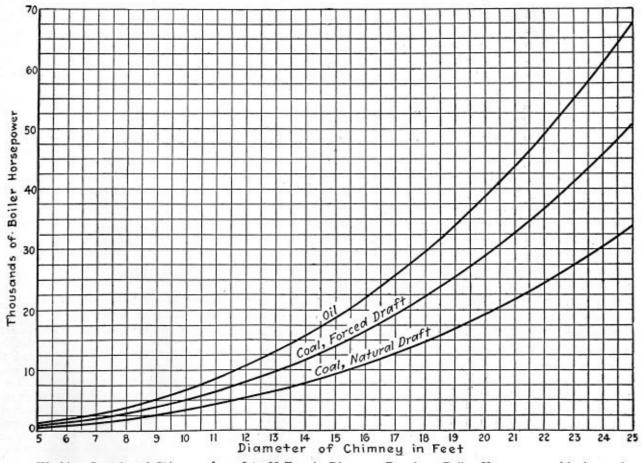

Fig. 17 .- Working Capacity of Chimneys from 5 to 25 Feet in Diameter, Based on Boiler Horsepower with Atmosphere at 60 Degrees F. at Sea Level

(Maximum capacity = 95 percent of maximum capacity with mean temperature of gases at 900 degrees F. Working capacity = 30 percent of maximum capacity at 600 degrees F.]. Weight of gases = 90 pounds per hour for natural draft, 60 pounds per hour for forced draft, and 45 pounds per hour for oil.)

the first approximation. The first approximation of heights appropriate to the listed diameters is given in column 7 and is made on the assumed mean temperature and gas acceleration loss. A close determination is now made of mean temperature in accordance with each combination of approximate height and diameter and of the actual loss due to acceleration of gases. This leads to a new series of heights as entered in column 15. A curve of heights as in column 15 is now drawn against the diameters of column 1 as the full line of Fig. 18 and simplifies the final choice. Such a curve shows the practical limits at each end of the series very decidedly.

It was pointed out by Deinlein that of a series of possible chimneys, the one whose product of diameter by height was the smallest would be the least expensive. These products are entered in column 19 of Table 2 and their curve drawn in Fig. 18 as the broken line. The lowest point in this curve occurs at 14 feet 6 inches diameter where the height is 289 feet. The author is indebted to Mr. George H. Gibson, Mem. A.S.M.E., for this information.

A problem frequently met with is that of modernizing and increasing the steaming capacity of a plant while using the existing chimney.

A curve of exit gas temperatures is first drawn and then a curve of the corresponding mean temperatures of the chimney gases as in Fig. 19. These are used to determine the characteristics of the chimney as in Fig. 20; and as this is based on weight of gases, it must be related to Fig. 19, which necessitates a curve of gas weight per horsepower depending on the curve of efficiency. The draft loss through the boilers is determined and plotted. The areas and arrangement of flues are carefully examined because desirable reduction of their draft loss can usually be made by redesigning them. The predicted flue draft loss added to the boiler draft loss nd to the vacuum necessary over the fire, will enable the

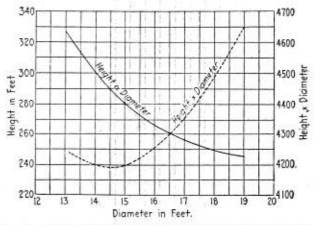

Fig. 18.—Chimney Study Giving a Series of Combinations of Height and Diameter

curve of draft required at base of chimney to be drawn as in Fig. 19. With the mean temperature of chimney gases, the static draft for different loadings is read from Fig. 2 and plotted.

The fraction of static draft for different fractions of maximum capacity is found from Fig. 1, and the equivalent draft for each percentage of boiler rating noted. The loss due to acceleration of gases is then found and deducted therefrom, leaving the available draft at the base of the stack at each percentage of rating at which the boilers might be worked. Curves are then drawn of these available drafts as in Fig. 20. The draft required at different ratings is read from Fig. 19 and enables the broken-line curve of maximum chimney load at different boiler-rating loads to be drawn in Fig. 20.

The actual boiler horsepower which the chimney will carry

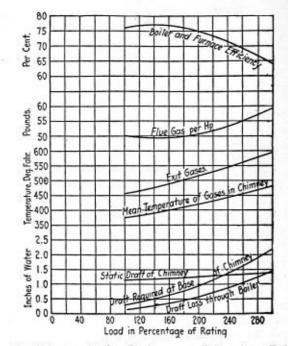

Fig. 19.—Chimney Study; Performance Data of an Existing Chimney

at different boiler ratings is obtained by dividing the total gas weights of Fig. 20 by the gas weight per horsepower of the curve of Fig. 19. To show this more clearly, the curve of Fig. 21 may be drawn. This curve emphasizes how the chimney capacity is governed by the draft loss of the boilers and flues. If the flues were enlarged, the chimney capacity would be greatly increased. This curve also shows that the capacity of the chimney is increased enormously if the boilers are run at low ratings owing to the much lower draft loss at low loads.

The requirements may be met by reducing the excess air, by improved methods of firing, by installing induced draft, or by adding more boilers and running at lower boiler ratings. The first and last methods increase boiler efficiency and save coal, while the second method increases the coal consumption by running at higher boiler ratings where the efficiency is lower.

Other examples are given in the complete paper which show that the system is as well adapted for finding approximate but reliable chimney sizes as it is for making more accurate studies of chimney characteristics for large and important plants such as the one immediately preceding.

# Discussion

THE discussion was opened by the reading of a communication from Julian C. Smallwood¹ in which he pointed out that the author's method was an elaborate structure based on two slender supports, namely, Menzin's coefficient for frictional resistance in chimneys, and the author's estimate of mean temperatures of chimney gases.

Menzin had assumed the hydraulic equation for friction to hold, although there was no experimental proof that for such large gas flows as those in present-day chimneys that it did hold; and had selected the coefficient 0.008 as a compromise between 0.012, from the crude experiments of Gale, and 0.006, from the limited data of Peclét, both obtained prior to 1890 and therefore scarcely up to date,

The author's calculations for chimney height were based on mean stack temperatures instead of temperatures at the base

⁴ Assoc. Prof. Mech. Eng., Johns Hopkins Univ., Baltimore, Md., Mem. A.S.M.E.

of the stack, which was a correct procedure. Curves were presented in the paper to show the relation between mean temperature of stack gases and temperature at base. These curves were based on experiments made at the Massachusetts Institute of Technology and still more recent ones at Johns Hopkins University. Professor Smallwood could not speak for the former, but having himself conducted the latter experiments, he wished to emphasize the fact that the temperature gradients obtained had been influenced not only by air infiltration through idle boilers but by leakage at the

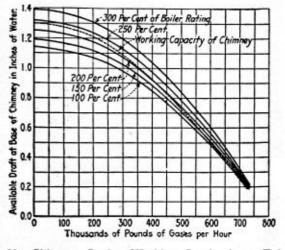

Fig. 20 .- Chimney Study; Working Load of an Existing Chimney at Different Boiler Ratings

joining of the breeching and the chimney. This possibly accounted for the rapid temperature drop of the gases upon leaving the breeching, as shown by Figs. 2, 3, and 4. As had been pointed out in the report of the Johns Hopkins tests, it was absolutely essential for correct chimney design that the mean stack-gas temperature be calculated with some degree of precision, and that loading of the chimney by cold air be prevented. If the author had given the Johns Hopkins tests much weight, his results would possibly be more applicable to chimneys leaking air at the base than to the tightly sealed chimneys of modern large power plants.

Professor Smallwood questioned the author's statement that the maximum capacity of a chimney was independent of its height. This might be true if the stack gases would only remain at a constant temperature; as a matter of fact they inevitably decreased, radiation alone being sufficient to account for this phenomenon. The higher the chimney, the lower became the temperature of the issuing gases. As the temperature fell, the density of the gases increased, and the increment of draft due to each increment of height became less and less. On the other hand, the frictional resistance per increment of height remained constant, and in consequence there was a limit beyond which the increased frictional resistance was greater than the increased draft, resulting in a lessening of available draft at the base, as well as in capacity.

Despite the preceding criticisms, Professor Smallwood considered that the author had made a real contribution toward the solution of the problem of chimney proportioning and that his method of arriving at definite results was by far the best yet presented. It was of the highest importance, however, that additional experimental data be obtained, and power-plant superintendents should cooperate in experimenting on large chimneys to determine friction losses, the factors with which they vary, and the laws relating them; determining the exact relation between temperature of gases and height of chimney; and investigating the influence of air infiltration, down drafts, stratification, eddy currents, etc. Until this was done, chimney design must remain much where it was.

T. A. Marsh² wrote that chimneys were not power generators and were not subject to classification on a horsepower basis. They fulfilled the same function as fans and should be rated by the same units of measurement, namely, gas volumes and pressures.

The large problem was one of judgment as to what variables to use. Such items as the flue-gas temperature as affected by operating conditions, friction losses as affected by fouling of boiler passes, quality of coal and provision for worst coal as affecting the weight of air, were all subject to considerable variation, and judgment based on ample experience was required to select the proper values. There was also the question of the probable operating conditions that might exist five or ten years hence in the plant in reference to plant development and growth, as well as that of the capital investment for plant expansion.

E. L. Hopping,³ who opened the oral discussion, said that some years ago he had occasion to design the stacks for a modern plant, and found that the various formulas available for that purpose gave stack diameters ranging from 8 to 12 feet for a given case. The old stack formulas, which were based on hand firing, would not apply to the great variety of conditions obtaining in stoker firing, and in this respect he felt that the author had presented something definite that could be depended upon.

Great care had to be exercised in making assumptions regarding gas conditions-whether they would be uniform throughout the stack or whether considerable excess air would filter in at some intermediate point. Further, radiation losses would be greater in steel stacks than in those built of brick unless the former were lined from bottom to top.

N. E. Funk⁴ said that while two of the fundamental quantities used in the author's method were assumptions based on scanty experimental data, he nevertheless believed that it would be found to yield more accurate results than anything

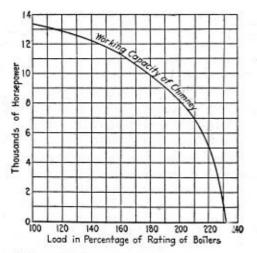

Fig. 21 .- Chimney Study; Reduction of Working Capacity of an Existing Chimney at Increased Boiler Ratings

else published on the subject. The formula for friction might be open to question as the friction varied with the condition of the surface, and the surfaces differed widely as regarded roughness. The velocity to be used in such calculations was that at the sides of the stack where the friction occurred, and not the average velocity of flow through the stack cross-section, which was higher.

A. G. Christie⁵ confirmed what Mr. Hopping had said in

² Ch. Engr., Green Engrg. Co., E. Chicago, Ind. Mem. A.S.M.E. ³ Engr., Philadelphia Elec. Co., Philadelphia, Pa. Mem. A.S.M.E. ⁴ Operating Engr., Philadelphia Elec. Co., Philadelphia, Pa. A.S.M.E. Mem. regard to the diversity of results obtained from various stack formulas. The previous summer, in connection with the design of chimneys for the pulverized-fuel-burning station being constructed in St. Louis, he had had some of his assistants gather a large amount of performance data from chimneys in modern plants in order to determine whether an empirical formula might be derived that would be suitable for the work in hand, and it had been found that practically every chimney considered had been designed, with certain modifications, according to Kent's original formula.

Professor Christie agreed with Mr. Funk that surface friction was involved as well as fluid friction. In the work which Professor Smallwood had conducted at Johns Hopkins, thermocouples having been found untrustworthy, a large resistance thermometer had been built to measure the average temperature across the chimney. This fitted the inside of the stack nicely and could be lowered from top to bottom. For a long time no explanation had offered itself as to the very great temperature drop that took place between the outlet of the boiler and the top of the stack; but at last it was found In his closure, the author said that he believed that Professor Smallwood had overlooked one or two points set forth in the paper. It was obvious that the maximum capacity being independent of the height was based upon having the same conditions in all cases, including the mean temperature of the gases. If comparison was being made of two actual or proposed chimneys of different heights, the appropriate mean temperatures would be found as directed, so that this point was fully taken care of in the paper.

Leakage of air at breechings did not impair the method presented in the paper because the designer must naturally base his calculations on the weight of gases going up the chimney.

No one deplored more than the author the lack of information on chimney performance, or would more heartily welcome exhaustive research. However, Professor Smallwood would see on further consideration, that the method was not based on the slender support of the meager information now available but simply utilized what knowledge was so far available. As shown in the paper, further research would enable

that the breeching had been cemented into the stack cold, and that heating had dished it inward from the chimney, leaving large openings through which cold air entered. Consequently the published results of the Johns Hopkins experiments would have to be used with a considerable measure of caution as they did not represent good chimney conditions.

While there were many variables involved in chimney design, Professor Christie concluded, all but a few were unimportant and could be neglected. Certain definite items such as velocity, mean temperature difference, and friction loss could be determined, and then three or four of the important variables might be selected and some real experimental data obtained on them which would make it possible to design a chimney with a reasonable degree of accuracy.

F. F. Uehling⁶ said that air infiltration between the boiler and stack, though not given much thought, was a serious matter. In the majority of the plants which he had had occasion to examine in this regard he had found that the  $CO_2$ percentage at the base of the stack ranged from 3 to 5 percent. When the gases left the boiler the percentage was from 10 to 12, which meant a tremendous infiltration of air, in fact, so much so that the stack was burdened with 100 percent more gas than it should carry away.

Others who briefly commented on the paper were Max Toltz,⁷ who welcomed the new method as one that would make it possible to design stacks rapidly and with accuracy; and W. B. Frost, who believed that the new types of airtight flues would do away with much of the uncertainties in design caused by air infiltration.

⁶ Prof. Mech. Eng., Johns Hopkins University, Baltimore, Md. Mem. A.S.M.E. ⁹ Pres. and Combustion Engr., Uebling Instrument Co., Paterson, N. J. Mem. A.S.M.E. ⁷ Mech. Engr., Toltz, King & Day, Inc., St. Paul, Minn. Past Vice-Pres., A.S.M.E. more accurate results to be attained by the use of the method. But to impugn the method because of lack of authoritative data was like suggesting that we discontinue the use of the micrometer until we have decided whether the inch or the meter is the better unit with which to graduate it so that it will be accurate.

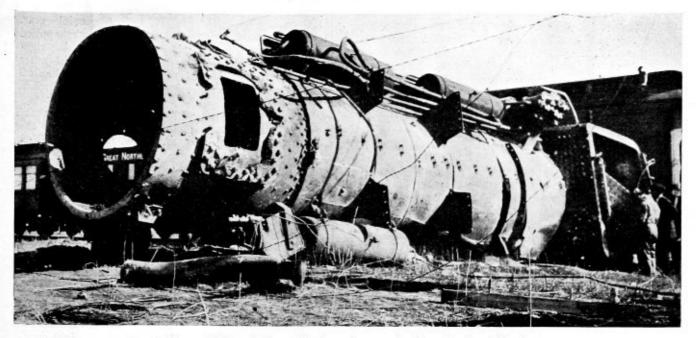

In preparing the curves for finding mean temperature, the curve of temperature drop No. 1 in the Appendix was given the greatest weight since it was the only one in which the weight of gases was even approximately known. As the weight of gases in the Johns Hopkins tests was not given, no considerable use could be made of them except in a very general way.

Mr. Marsh had drawn attention to the variables to which consideration must be given, and these should always be borne in mind in determining chimney sizes. The various allowances which experience suggested were easily taken care of in using the proposed method.

Mr. Hopping had well emphasized the chaotic state of the art. If reliable results were desired, it was imperative that gas weights be used rather than boiler horsepower. When this was done, no trouble was experienced such as that caused by the different proportions of excess air in hand firing and modern machine firing.

In reply to Mr. Funk, the lack of experimental data affected the accuracy obtained by the use of any method of chimney computation, but in no way detracted from the value of the method itself. So far, friction had been based on volume passing and consequently on average velocity, and that really seemed to be the most convenient way, as it included both surface and fluid friction.

Replying to Professor Christie, the author said that further chimney experiments should include gas analyses at different

General View of Great Northern Locomotive No. 320 after Wreck

# Fatal Boiler Explosion Caused by Low Water

Overheated Crown Sheet Failure on Great Northern Locomotive Causes Loss of Three Lives

O^N another page of this issue appears a first-hand account of a Great Northern locomotive disaster that occurred April 16 near Minot, North Dakota. The suggestion was made by the writer of this communication that a detailed report of this explosion would be of special interest to many of our readers who are familiar with the circumstances connected with the disaster. For this purpose, A. G. Pack, chief inspector of the Bureau of Locomotive Inspection, has supplied the details of his official investigation and report which are published below.

On April 16, 1923, at 4:20 p. m., the Great Northern locomotive 3201 left Minot Yard, N. D., in charge of engineer C. C. Bonnewell and fireman Fred Remus, en route to Williston, N. D. The train proceeded to Des Lacs, N. D., approximately 14 miles, where a stop was made for water, then proceeded to a point about  $1\frac{1}{2}$  miles east of Roach station, approximately 27 miles west of Minot, operating on a grade varying from 0.6 of 1 percent to 0.72 of 1 percent, when the boiler exploded causing the death of brakeman Thorsdahl and the fatal injuries of engineer Bonnewell and fireman Remus, who were riding in the cab of the locomotive at the time of the accident.

This was a large Mikado type locomotive constructed by the American Locomotive Company in March, 1919. The

heights, so that the draft loss and temperature drop within the chimney could be more definitely related to gas weight than can be done at present.

The author agreed with Mr. Uehling as to  $CO_2$  readings and excess air, and could confirm his experience as to serious air leakage losses in very many plants. The use of  $CO_2$ recorders should be increasingly encouraged; and in many cases, a  $CO_2$  recorder connected to the chimney would be very valuable.

It was very interesting that Mr. Toltz had used the method

force of the explosion tore the boiler from the frame and running gear, hurling it forward for a distance of approximately 190 feet, where it first struck ground on the back head of the boiler, making a dent in the earth about three feet deep, then rebounding approximately 70 feet, striking the ground with the front end, rebounding the second time approximately 60 feet, striking on the right top side of the knuckle of the back head, finally coming to rest on the right side of boiler at a point 330 feet from the point of explosion. The running gear was not derailed.

Engineer Bonnewell's body was found directly opposite the point of explosion on the right side of the track against a telegraph pole, approximately 30 feet from tracks. Brakeman Thorsdahl's body was found on the right side of the track, near the right-of-way fence, about 30 feet back from the point of the accident. His left arm was torn off and found near the right-of-way fence about 75 feet ahead of the point of accident. Fireman Remus' body was found about 50 feet back from the point of the accident on the left side of the track, near the cab of the locomotive.

#### CONSTRUCTION OF FIREBOX

The boiler was of the extended wagon top type, with a radial stayed firebox and combustion chamber. The com-

in comparison with others. The advisability of having a simple method could not be gainsaid, and simplicity was an outstanding feature of the system.

Replying to Mr. Frost, the author said that he had found many overloaded chimneys that were not overloaded with useful work but with unnecessary air. Unless flues were airtight, the chimney would be unnecessarily overloaded.

Chimneys should in general be designed on a basis of gas weight. The curves based on boiler horsepower were only intended for approximate or preliminary work.

317

bustion chamber door, side and crown sheets were constructed of steel plate 7/16 inch in thickness. The flue sheet and inside throat sheet were 9/16 inch in thickness. The crown and side sheets were of one-piece construction. The seams in the door hole as well as the seam between the crown sheet of the combustion chamber and firebox proper were autogenously welded, while all the other seams were riveted.

The crown sheet including the combustion chamber was supported by 20 longitudinal and 31 transverse rows of radial stays  $1\frac{1}{8}$  inches at the crown and roof sheet ends with body reduced to 15/16 inch, spaced  $3\frac{7}{8}$  inches by 4 inches. The first six longitudinal rows of stays on each side of the center extending from the sixth transverse row to the door sheet had button heads. All other stays had hammered heads. The first four transverse rows were flexible type stays. Other staybolts were spaced  $3\frac{7}{8}$  inches by 4 inches and were  $\frac{7}{8}$  inches in diameter.

The locomotive was equipped with a Schmidt type superheater, having 45 units. The firebox was equipped with four 3-inch arch tubes, carrying a brick arch. The firebox was not equipped with fusible plug or low water alarm.

### EXAMINATION OF FIREBOX

Investigation disclosed that this explosion was due to the firebox crownsheet having become overheated, due to low water.

The crownsheet of the firebox was overheated from the flue sheet to the door sheet and from the tenth longitudinal row of stays on each side of the center at the flue sheet to the sixth longitudinal row on each side of the center at the door sheet. This made the overheated area approximately 127 inches in length, 75 inches wide at the flue sheet and 48 inches wide at the door sheet. The overheated area showed a distinct blue color, the line of demarcation being well defined and showed water to have been approximately 7 inches below the highest point of the crown sheet.

#### FAILURE OF FIREBOX

The initial failure apparently took place in the area between the sixth and ninth transverse rows from the flue sheet near the center of sheet, the crown sheet pocketing down at this point, pulling over button heads of stays and enlarging holes to a maximum of approximately 17% inches and sweeping toward the back end of the firebox until the eighteenth transverse row of stays was reached, where the initial rupture occurred. This rupture follows a straight line transversely through 29 holes in the crown and right side sheet, continuing down to the mudring. The top of the flue sheet ruptured through the line of the upper row of small flues from the left side to the right top corner of the flue sheet in the combustion chamber and continuing downward close to the edge of the flue sheet flange. It then followed the line of the inside throat sheet flange until the mudring was reached, where 18 rivets were sheared and sheet torn free at this point. The top part of the flue sheet straightened out and still adhered to the crown sheet. About two-thirds of the crown sheet was blown down and pulled a portion of the flue sheet, combustion chamber and right side sheet with it and partially folded back against the left side sheet, leaving the left side sheet intact. These sheets pulled away from 333 staybolts and 406 crown stays, making a total of 739 stays, from which the sheets pulled away. The flue sheet pulled from the top row of small flues, 16 in number, and two superheater tubes.

The autogenously welded seam in crown sheet close to point where pocketing of crown sheet occurred was not affected.

# APPURTENANCES FITTED TO LOCOMOTIVE

The locomotive was equipped with a Franklin pneumatic fire door which was torn off at the time of the explosion. It was also equipped with a standard stoker, which was badly damaged, but still adhered to the running gear.

The boiler was equipped with three gage cocks applied in the water column, this column being located on the right side of the back head, closely adjacent to the right water glass, but not connected to it. The column was broken off flush with the back head but openings through the broken parts were clean.

The boiler was equipped with two water glasses, both of which were torn off, the bottom cocks being applied to the back head with top connections applied in the wrapper sheet about  $5\frac{1}{2}$  inches forward from the knuckle of the back head. The openings of both water glass connections in the boiler were clean. The right water glass mountings and bracket were found a short distance from the boiler. Left water glass mountings were broken off at the boiler but still adhering to bracket attached to the boiler. Both stems to right water glass cocks were badly bent and damaged. The bottom water glass cock when found was open approximately one turn. The upper cock was open approximately two turns. The openings in mountings to right water glass were clean.

The stems of the left water glass cocks were broken off at the packing nuts and to determine the openings of valves the mountings were sawed apart. The lower valve was found to be nearly seated on one side of the valve and a slight opening found on the opposite side, which would make a very sluggish movement of water in glass and would not require very much sediment to obstruct the entire flow of water through this valve. The opening in the left top water glass mounting was found approximately two turns open.

There was a small piece of gasket rubber hanging loose in the stuffing box to the lower water glass cock of left water glass when same was inspected.

The lowest readings of water glasses and gage cocks were checked on locomotive 3,204 of the same class without leveling the boiler and found to be as follows: Right water glass  $4\frac{1}{4}$  inches, left water glass  $4\frac{1}{2}$  inches and the lowest gage cock 4 inches above the highest point of the crown sheet.

The stems of all gage cocks were broken off at the packing nut and the gage cocks were removed from the column and dismantled to determine their condition and were found clean.

The water column was also examined and found clean.

The condition of gage cock dripper could not be determined on account of the dripper being filled with clay and pipe broken off and not found.

The steam gage was demolished and could not be tested. The condition of the right boiler check could not be determined on account of the boiler lying on its right side and the check could not be removed, the boiler not having yet been picked up by wrecking crane.

The left boiler check was examined and found in good condition and had 3%-inch lift. Both boiler checks were equipped with angle stop valves to boiler. Left check was found open, condition of right check not determined.

# CONDITION OF TANK

The tank was inspected and found practically clean. Tank wells were equipped with perforated strainers which were found clean. Both tank valves are of the plug cock type, and when inspected right valve was found clean and open, left valve was found clean and closed. Tank hoses were new and in good condition. Strainers used in strainer boxes in feed water pipes were clean. Hancock non-lifting inspirators size 11 were used. Right number 419,452 was damaged so that it could not be tested under steam, but was dismantled and all tubes and valves found in good condition except forcing tube, which was broken, and stem on steam valve which was also broken, no doubt from force of explosion. When inspected, steam ram to right inspirator was found open. Left No. 419,879 was applied on locomotive 3,204 of *(Continued on page 326)*

The double event during the week of December 3 to 8 of the annual meeting of the American Society of Mechanical Engineers and the Power Exposition to be held at the Grand Central Palace, New York City, will give those interested in the design and construction of boilers an opportunity to check up the year's developments in the field of power.

During the week the Power Test Codes Committee will hold public hearings on the Code for Stationary Steam Generating Units and on the Code for Locomotives at both of which the work of the committee will be open to general discussion.

The recent annual meeting of the National Safety Council, held at Buffalo, N. Y., brought home to delegates from every important industry, insurance company and railroad in the country the necessity of decreasing the number of accidents that every year take their toll of lives from the man-power of the country. In 1922, 75,000 men, women

and children were killed in accidents, many of which might have been prevented by the application of the ordinary rules of caution and safety that have been laid down for practically every branch of industrial and civil activity and occupation.

There are now fifty organizations in as many cities spreading the gospel of safety with excellent results. It is a significant fact that of all promoters of the safety idea the railroads have accomplished more than practically any other industry in lessening the fatalities caused by the pursuance of its function in the community.

Railroad shops and boiler shops in general have been leaders in the safety movement, but resolutions applying to industry adopted by the Safety Congress and given below indicate ways and means for further promoting industrial safety.

"The safeguarding of all dangerous machinery and places in industry and elsewhere according to standard methods of proved value.

"The development of industrial equipment and processes along lines of inherent safety for the double purpose of eliminating accident hazards and increasing production efficiency.

"The education of all workmen and their supervisors in safe methods and habits of work."

Reports from the Far Eastern division of the Department of Commerce indicate that rebuilding operations in Japan will be extended over a period of from five to seven years. This activity will be accompanied by a steady demand on outside sources of supply for construction materials, machinery and power units. Plans and specifications for the rebuilding of the affected areas are now under way, and at this time the budgets for the necessary work are being considered by the Japanese Diet.

The opportunity for American manufacturers to supply a great deal of the material required for reconstruction is great —particularly heavy machinery, factory equipment and boilers. Here is an opening to manufacturers in this country with stock boilers on hand to supply a foreign demand in which the time factor is vitally important and, at the same time, establish a firm foundation for future business.

The financial condition of Japan is generally satisfactory, so that with the insurance adjustments that will be applied towards the purchase of equipment American manufacturers can feel secure on the question of credit.

The United States Department of Commerce in Washington will supply details of industrial requirements in Japan.

Notice has been received by C. W. Obert, secretary of the American Society of Mechanical Engineers' Boiler Code Committee, 29 West 39th street, New York, that the new boiler regulations for India are now in the final stage. Copies of these regulations will be received in this country within a short time, and will be published in THE BOILER MAKER. They will be particularly interesting to American boiler manufacturers who, it is suggested, should exercise discretion in the meantime in meeting stock orders from agents in India, especially if these stocks are liable to be unsold by January 1, 1924, when the new regulations will go into force. This, of course, assumes that such stock sizes will not meet the new conditions imposed.

# Engineering Specialties for Boiler Making

New Tools, Machinery, Appliances and Supplies for the Boiler Shop and Improved Fittings for Boilers

# Plate Bending Roll for Heine Boiler Shop

THE Hilles and Jones Works of the Consolidated Machine Tool Corporation, New York, has recently completed an exceptionally large boiler plate bending-roll to be installed in the St. Louis shop of the Heine Boiler Company. This No. 9 bending roll is a new and improved heavy-duty hinged-housing machine, designed for handling plates up to 15% inch thick and rolling these to relatively small diameters.

The distance between the housings is 26 feet 6 inches to provide ample length for rolling plates 26 feet long.

The machine is provided with two interchangeable upper rolls, the larger upper roll 36 inches in diameter and the smaller 30 inches in diameter. The 36-inch upper roll is used when rolling the heaviest plate and to ordinary diameters, while the 30-inch upper roll is used when rolling plates to small circles of about 36 inches diameter. The lower rolls are each 22 inches diameter, and the roll journalbearings in the housings are bushed with bronze.

The roll forgings proper are all made of open hearth forged steel, and the upper rolls have a solid forged extension which provides for counterbalancing when the back housing is dropped down for the removal of plates rolled to full circles.

The rated capacity for the machine is a pressure of 2,500,-000 pounds, this being a very conservative rating as the factor of safety is high.

The housings and all driving gears are steel castings.

The housing bed plates and gearing bed plates are semisteel castings of box section design.

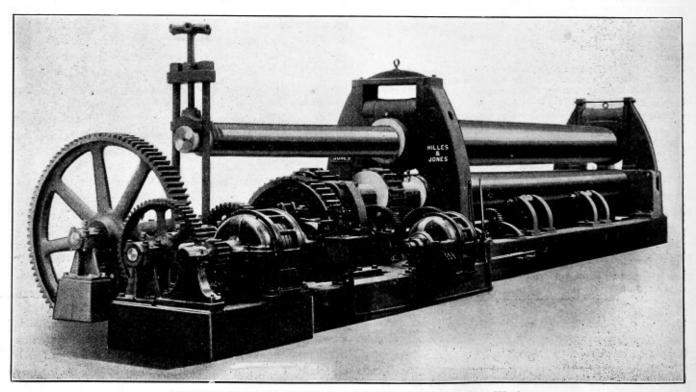

The upper roll is supported from the roll necks which are fitted in trunnions having bearings bushed with bronze. The trunnions are carried in yokes, the back yoke being a steel casting while the front yoke, which supports the upper roll when counterbalanced, is a steel forging machined to shape. The raising and lowering of the roll is secured through a worm and worm wheel drive, and is designed so that both ends of the upper roll may be raised or lowered simultaneously or one end held stationary while the other end is raised or lowered.

This arrangement for operating the upper roll is necessary in rolling plates to conical shapes, and is often found advantageous in ordinary boiler shop practice. The worms are of machined cast bronze and run in enclosed bearings designed so as to provide for lubrication with either heavy oil or grease. The worm wheels meshing with the worms are made of cast steel and have teeth cut from the solid metal.

The driving pinions on the lower roll necks are steel castings shrouded to the pitch line. These pinions are both driven from a wide-faced cast steel gear shrouded to the pitch line and this driving arrangement conveys power directly to both lower rolls.

The machine is geared for two speeds—a slow speed for handling the heavier plates and a high speed for handling lighter plates. The control of the speeds is by hand levers direct connected to positive clutches.

Two substantial roller supports are provided for the lower

Hilles and Jones Bending Roll Specially Built for Boiler Work

rolls and each support carries four forged steel rollers finished to 7 15/16 inches diameter. The rollers are carried in closed end bearings which design provides for lubrication of the rollers by means of large grease cups. This arrangement not only insures lubrication but also keeps scale and dirt from clogging and stopping the action of the rollers.

All high-speed shafts have bearings bushed with bronze and substantial outboard bearings are provided to carry the outer end of all driving shafts so that there are no overhanging gears.

The machine is operated by two motors, a motor of 125 horsepower is used for driving the lower rolls and a motor of 60 horsepower for raising and lowering the upper roll. The weight of the machine is 415,000 pounds.

The need for a tool of this sort arises from the increasing demand for exceedingly high pressure boilers of large capacity, requiring the use of thick plates in large sizes for the cylindrical shells. The possession of equipment of this sort will enable the Heine Boiler Company to accept and promptly execute orders for large capacity high pressure boilers of any of the several types which it builds.

# Light Weight Electric Drill

THE electric drill illustrated, which weighs less than five pounds, has been placed on the market recently by the Argyle Railway Supply Company, Chicago. This tool will drill holes up to 3% inch in diameter and is said to be practically non-stallable. It is well adapted for many drilling operations in railroad shops, including stay bolt tell-tale holes, miscellaneous drilling in car repair work and battery work. A special Westinghouse motor is used which will operate on either alternating or direct current, the motor running at high speed on light loads and slowing down to the required amount when drilling larger holes. The free speed is 2,000 revolutions per minute and the full load speed 850 revolutions per minute which is approximately the proper cutting speed for a 3%-inch drill.

The field windings are coated with a special compound and baked 90 hours, resulting in a field coil of one solid mass

The Titan Electric Drill is Convenient to Handle and Operate

with practically no possibility of the wires becoming loosened from each other. This adds to the insulation properties, making the armature practically indestructible except from accidental mechanical abrasion. The armature is not injured by immersion either in oils or in water except as this might corrode the metal parts.

The ventilation of the drill brings the cool air into the back both in the upper and lower branches of the handle, assuring that the handle grip will always remain cool and that the incoming air will be distributed to all parts of the motor. The motor field is held away from the housing by ribs which permit the air to pass around that and also around the armature to cool these parts in the most effective manner.

The air is discharged in the front of the housing, tending to blow away from the drill any dirt or particles which might be raised in drilling operations.

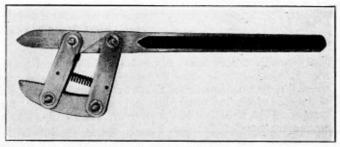

The Titan drill runs only when the operator is actually gripping it and drilling. The position and operation of the switch is natural and the ease of release without shifting the hand makes it possible to stop the motor without shifting the position of the drill, a frequent cause of breakage. This switch was developed for the Titan drill by the Cutler-Hammer Manufacturing Company. The drill is steel armored, designed to be non-breakable, and all parts are riveted together so that there is no danger of the contacts becoming loosened or the plug becoming broken. A durable cord is used which does not lead into the motor itself and can therefore be replaced without the services of an experienced electrician.

A simple and effective lubricating system is used, the two armature bearings and the drill chuck bearings having bronze bushings and spring oilers which retain a considerable amount of lubricant. If the drill is thoroughly oiled for the first few hours of operation it is said to require lubrication only occasionally thereafter.

The thrust in drilling is taken up on a ball-bearing, working between two hardened and ground steel surfaces. The gears are packed in grease. The pinion is of steel, cut directly on the armature shaft and meshing with a bronze gear. The teeth are cut helical, adding to the strength and smoothness of operation. The gear ratio is  $7-5\frac{1}{2}$  to 1. This odd number is chosen purposely to prevent the same pair of teeth on the gear and pinion always meeting. The chuck is of the Goodell-Pratt keyless type requiring no tool to open or close it. To prevent the armature from turning when opening or closing the chuck, it is only necessary to press the spring stop into the slot in the end of the armature shaft and the chuck may then be turned without offering any difficulty.

# Self-Adjusting Wrench

A NEW wrench, known as the "Roberts" type, which does away with the usual screwing up and down adjustment by means of a set screw to make it fit an object, has been put on the market by the Greater Service Electric Company, Newark, N. J. Using only one hand with the new wrench, it is simply necessary to place it over

New Wrench with Quick Adjustment Feature

the object and it grips instantly. It is stated that the wrench never slips—the harder it is pulled the stronger it grips, and at any angle. It also works with a new ratchet action which makes it easy to work in tight places.

The wrench is drop forged from high speed carbon steel. In its present 12-inch size, this wrench will handle any shape article from small nuts to one inch pipe. Its price is lower than the average good wrench, and the company states that the time saved by a mechanic in an ordinary day's work would pay for the tool. It is also guaranteed against all imperfections.

# Questions and Answers for Boiler Makers

Information for Those Who Design, Construct, Erect, Inspect and Repair Boilers—Practical Boiler Shop Problems

Conducted by C. B. Lindstrom

This department is open to subscribers of THE BOILER MAKER for the purpose of helping those who desire assistance on practical boiler shop problems. All questions should be definitely stated and clearly written in ink, or typewritten, on one side of the paper, and sketches furnished if necessary. Inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

# Stack Bonnet and Tapering Casing

Q.—Will you kindly publish how to develop a stack hood or bonnet, and how to layout in one piece a sand dome casing?—S. C. D.

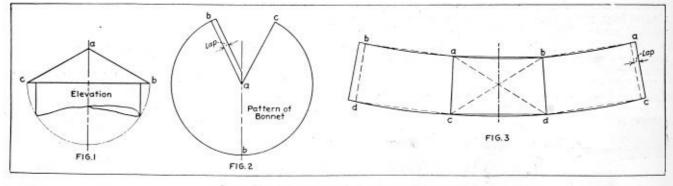

A.—The layout of a stack bonnet is shown in Figs. 1 and 2. Reproduce the elevation to the required dimensions, which shows the bonnet in the form of a cone. With the dividers or trammels set to a radius equal to a-b, Fig. 1 draw a circle as from point a, Fig. 2. Make the arc lengths between b-b

# **Renewing Side Sheets and Tubes**

 $\Omega_{\rm e}$ —Please tell me how to put on  $\frac{3}{2}$  side sheets which are now usually required over a fire; that is, how to get the holes spaced in the new sheet and the holes in the boiler spaced. Some of our repair boiler makers lay off the holes in the boiler and have them drilled while getting out new ones at the shop; others put holes in the new sheet and lay off from that to the boiler, which is slow but sure. Others do not know how much lap to give. Also please tell me the best system of taking out flues of vertical and other boilers, which is usually the main repair work.—M. E. H.

A.—In applying side sheets or new sections of side sheets, two methods are applicable. Some repair men remove the damaged section, using the oxygen torch for cutting where possible without damaging the outer firebox sheets. The old plate is straightened and used as a template for marking off the new patch. The edges of the plate after cutting with the gas torch are left with a crust which must be scraped or chipped off.

Overlapping edges at the corners of the patch should be thinned down by scarfing. The stayholes in the new patch should be punched smaller than the required stay diameter and afterwards reamed out in place to insure alinement of the

Stack Hood Layout and Frustum of a Cone

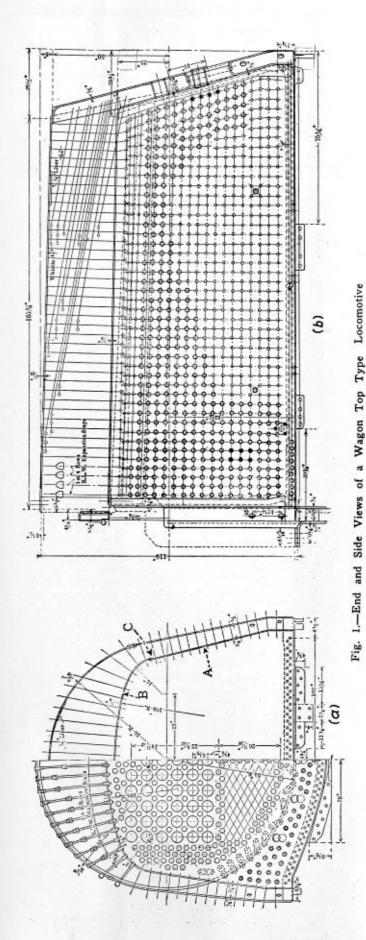

and *b-c*, Fig. 2 each equal to the length of the semi-circle, Fig. 1, which may be done by using a circular measuring wheel. If such an instrument is not available space one-half of the semi-circle into equal parts and use the arc lengths for spacing off the stretchout in the pattern. The circular length around the base of the cone, Fig. 1, equals the product of the diameter and 3.1416. Thus, if the diameter *b-c* equals 14 inches, the circumference of the base equals  $14 \times 3.1416$ = 43.98 say 44 inches, to which must be allowed material for the lap.

Fig. 3 shows a short and an approximate method for developing a frustum of a cone when the taper is very small. Lay off an elevation of the frustum a-b-c-d and on each side reproduce an additional one, thus locating four points as b-a, b-a at the top and d-c, d-c at the bottom for drawing in the camber lines. A pliable piece of bar or strap iron or batten may be placed on these points and the camber lines drawn in. Make their lengths equal to the circumference of the upper and lower base circles and allow for lap. A traveling wheel can be used for measuring these lengths. stays. Rivet or patch bolt holes can also be drilled out in place. The lap around the seams should equal 1 inch. Where the top seam is not subjected to stress, it may be welded as that construction avoids overlapping plates, which waste away on the fireside.

#### LAYING OUT SHEETS

In Fig. 1 is shown an end view (a) and side view (b) of a wagon top firebox in which the side sheets A are riveted to the crown sheet B at C. Where such drawings are available for the boilers to be repaired the dimensions given should be checked for any changes that may have been made. From the drawing the new side sheets can be laid off to the dimensions given, and the new sheet fabricated while the old one is being removed. Care in handling this work must be taken to insure accuracy as the slightest variation in rivet or stay spacing will result in a loss of the plate.

Where a firebox is made up in the way shown in the illustration, it is advisable to renew the entire side sheet, as this overcomes the need of two lapped seams.

The methods followed in such work depend somewhat on the type of boiler; in general firetubes are removed by first cutting off the bead around the tubes and then to split the tube back 1 or 2 inches with a cape chisel or a rectangular tool called a crosscut. The split end of the tube is then flattened on itself at each end so that it can be drawn through the tube hole.

Fig. 2 shows a view of a tube and the method of splitting it; a tool of the form shown in Fig. 3 is then driven between the tube and plate forcing the split ends together as shown in Fig. 4.

Where an entire new tube installation is required and if the tubes can be removed through the manhole at the top or bot-

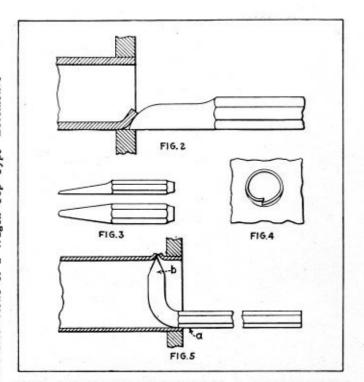

Fig. 2.—Method of Splitting Tube. Fig. 3.—Tool for Forcing Split Ends Together. Fig. 4.—Split Ends after Forcing. Fig. 5.—Tool for Cutting Tubes

tom of the boiler, the tubes can be readily cut out with a tool of the form shown in Fig. 5. The heel of the tool rests on the tube sheet and the lever arm a is brought down causing the cutting edge b to tear and cut out the tube, thus completing the operation.

There are several good rotary tube cutters used in cutting off the tubes, and by their use considerable time and labor is saved.

# Method for Removing Large Oil Tank Bottom

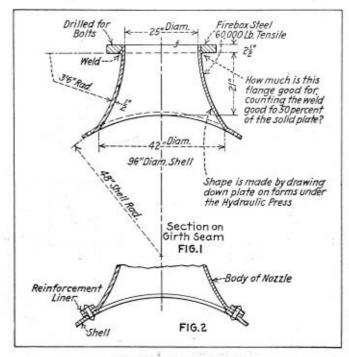

Q.-Would you please inform me as to the proper way to take out and replace a new bottom on a 90-foot steel fuel oil tank with regard to saving time on the job.--A. V. J.

A.—As in all repair work, the best means of handling a job depends on the conditions under which the repairs can be handled. In this case, we cannot give definite information, since we do not know how the tank is situated for carrying out such a major repair. If you will give further data we shall be pleased to help you, if possible, in an early issue of the magazine.

# Pressure on Nozzles

Q.—How can I calculate the pressure which the large steel nozzle as shown in the sketch will stand safely; that is, what working pressure, or how thick to make the nozzle to stand a certain pressure. The tensile strength of the steel is 60,000 pounds per square inch and is firebox grade, so as to flange easily on a fur post press. The finished thickness is ½-inch after pressing and drawing duwn to final shape. The shape is just the same as the standard "Tavlor" or American Spiral Pipe Company's regular design of noz les as used on A. S. M. E. beilers. What is the rule used for these smaller size nozzles? These nozzles are drawn from one round plate and without seams or welds, life the smaller cores mentioned. For 100 pounds pressure do you think any reinforcement is required for the outside of the rivet flange as shown in Fig. 2? If so, how should the reinforcement be figure?—C. P.

A.—To my knowledge there is no formula for finding the allowable working pressure on the nozzles shown in Fig. 1. A close approximation is the truncated cone formula given

Details of Boiler Nozzle

in Par. 231 of the A.S.M.E. Boiler Code. In the use of new constructions of this kind, the procedure is to make special tests of several samples, and record all deflections as the pressure is applied. Manufacturers of nozzles of smaller sizes have done this, from which standard sizes for different working pressures have been adopted. These data are given in the A.S.M.E. Code in tables of flange fittings; which cover those made of cast iron. An allowable variation of 20 percent from the flange thickness given in these tables may be made for cast steel and forged steel fittings; leaving the drilling for bolt holes unchanged. For pressures above 250 pounds per square inch, the flange thickness of the bodies shall be increased to keep within the same deflection limits and to give at least the same factor of safety as the fittings.

#### NOZZLE CONNECTIONS

The connection of the nozzle to the shell comes under the rules applied to dome connections. The A.S.M.E. Code specifies in Par. 194 the following: When the maximum allowable working pressure exceeds 100 pounds per square inch the flange of a dome 24 inches or over in diameter shall be double riveted to the shell. The flange of the nozzle tends to stiffen and compensate for the loss in strength of the shell, due to the removal of the plate for the nozzle opening. A reinforcing liner should be provided and riveted to the inside of the shell. Such reinforcements may be calculated as explained for manhole reinforcements or liners; as given in Par. 261 of the A.S.M.E. Code. No reinforcement is needed as you have shown in Fig. 2.

# BUSINESS NOTES

The Blacker Engineering Company, Incorporated, Grand Central Terminal, New York City, manufacturer of Blacker blacksmithing hammers, have opened an office in Pittsburgh at 421 Wood street with George Hesse as district manager.

The Linde Air Products Company, New York, recently started continuous operations in its new plant at Tulsa, Okla. Oxygen will be extracted from the air by the liquefaction process. The plant is also able to reclaim the nitrogen and separate the rare gases, argon and neon. C. A. Kennedy is operating superintendent. A Prest-O-Lite plant, for the manufacture of welding and cutting gas, is also planned for the same locality.

The Industrial Works, Bay City, Mich., which was established in 1873, celebrated its fiftieth anniversary on October 13, at Bay City. The celebration included a sales conference of all representatives of the Industrial Works from all principal points of the United States, Canada, Cuba and South America. Another feature was a test of a 200-ton wrecking crane which had been built for the Norfolk & Western. The Industrial Works was started in 1873 with a working force of 30 men in a factory building 75 by 100 feet. The plant today covers 29 acres of ground, and includes 59 buildings with 440,000 square feet of floor area, 5 miles of railroad track and employs 1,800 men. The 59 buildings include a foundry and pattern, blacksmith, boiler, bucket, car, canopy, electrical, paint, pipe and machine shops, each of which is a complete unit. Besides there is a pattern storage building, an employees' restaurant, a garage, and an office.

Charles Piez, president of the Link-Belt Company, Chicago, announces the purchase of the Meese & Gottfried Co., of San Francisco, Los Angeles, Seattle and Portland. For the past ten years Link-Belt Company has been distributing its products on the West Coast through its subsidiaries, the Link-Belt Northwest Company, of Seattle, and the Link-Belt Pacific Company, of San Francisco. The improvement in distributing facilities effected by the consolidation, and the additional manufacturing facilities acquired, should give the rapidly-growing industries of the Pacific Coast highly economical and efficient service. The new organization will be known as Link-Belt Meese & Gottfried Company, with headquarters at San Francisco. The officials will be: Charles Piez, chairman of the board; B. A. Gayman, president; Harold H. Clark, vice-president and sales manager; Leslie W. Shirley, treasurer; Richard W. Yerkes, secretary.

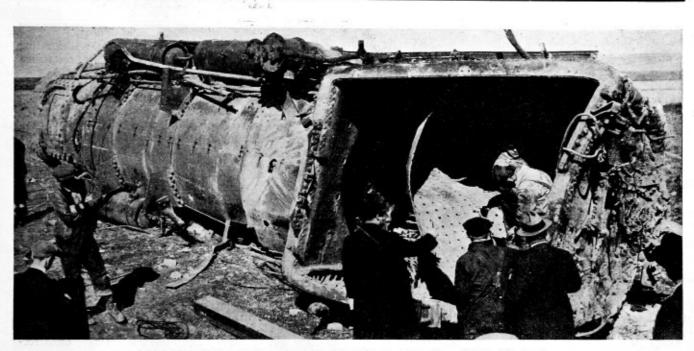

The Mahr Manufacturing Company of Minneapolis, Minn., manufacturers of rivet forges, torches, furnaces and kindred oil burning equipment, has moved its New York office from 56 Murray street to larger quarters at 42 Murray street. Ray G. White is the direct representative of the company at New York.

The Westinghouse Electric & Manufacturing Company at their South Philadelphia Works has established a General Engineering Division which will be devoted to the study of central station and industrial plant problems, which involve the application of steam power apparatus such as steam turbines, condensers and reduction gears. This department will also co-operate with the sales organization in providing engineering service to purchasers of this equipment.

The main office in Tokio, Japan, of Roku-Roku Shoten having been destroyed, requests are made to manufacturers in the United States to send to the company's branch office at Osaka, street address Enokojima Nishiku, complete catalogs and prices to replace their files. S. Noda is president of the company.

Firebox Wreckage after Great Northern Locomotive Low Water Explosion

# Locomotive Boiler Explosion Caused by Low Water

O^N April 9, 1923 a serious and unusual locomotive boiler explosion occurred near Roach, North Dakota, about twenty-five miles west of Minot, on the main line of the Great Northern Railway. Three men lost their lives in this explosion; the brakeman was killed instantly, the fireman died while being taken back to Minot and the engineer died the following day at a hospital.

This locomotive, No. 3201, one of the largest and newest, built for heavy freight service on the G. N. line, was one of several of its type built during the war while the roads were under government control. It left the Minot terminal on its fateful trip west at about 3 P. M. April 9 and two hours later the shocking news reached Minot of the disaster, with the casualties above mentioned. This boiler was subjected to a hydrostatic test just shortly before the explosion and was carefully inspected on the fateful day before leaving the Minot roundhouse by a federal inspector, who happened to be present on that day.

Éxamination of the firebox showed that the crown sheet had been badly burnt and all other indications showed that the explosion was caused by low water in the boiler; the engineer, however, who remained conscious until he died, emphatically denied this and stated that the water glass registered not less than two inches just two minutes prior to the explosion.

The railroadmen of Minot would be glad to receive a more complete and detailed report of this accident, and those of us who are subscribers to THE BOILER MAKER have been eagerly watching the magazine but no report has so far appeared.

Minot, N. D. ED. DINGFIELD.

Editor's Note:-The official report of the Bureau of Locomotive Inspection dealing with this disaster appears on page 317 of this issue.

# Failure to Live Up to Construction Rules a Source of Unfair Competition

THE Boiler Code was submitted to us by the A.S.M.E. and the commissions appointed by the different states as a rule and guide for the construction of boilers.

Recently I was in a shop and investigated the class of work and conditions under which boilers were being built at this particular plant and I will say that I am very much surprised and astonished at the class of work that was being allowed and let pass.

There was no excuse for such a poor grade of work except that the concern manufacturing the boilers was looking for production and to keep the overhead down, thereby constructing an inferior grade and class of boilers. I was at the shop for three and one-half days during working hours and I saw an insurance boiler inspector there three days, but never saw him make an inspection but merely take the melt number of the plates. He evidently does not follow up the construction and I am absolutely sure he does not make the concern comply with the Code requirements. These are some of the interesting items that I saw but of course there were numerous others.

 Sheets and butt straps were not taken apart and burrs and chips removed after drilling and reaming.

 Flue beads were cracked but were hammered over to hide cracks and checks.

Holes in cross braces were cracked from rivet or bolt hole out.

 Holes in barrel sheets were not drilled and reamed straight and some were out of alinement from 12 to 15 degrees.

Back head sheet around corner had a very bad crack at the scarf and was not properly welded.

Instead of calking sheets they were plugged straight back to fill up bad cracks and joints which were caused by not laying up the sheets and heads.

7. There was a heavy acetylene burr where the firedoor holes were burnt out and the sheets were bolted and riveted to the firedoor ring without removing the burr.

8. Staybolts and rivets were loose in the sheets.

Backhead braces were bent very crooked and allowed for unnecessary expansion.

10. Cross braces were loose and showed considerable slack.

11. Sheets were planed or milled or chipped as required by Code.

12. Sheets were not properly laid up before riveting. The mudring corners both inside and out were not laid up, nor the other sheets. In order to make a good job, it is necessary to heat these corners and lay up the material.

13. The sheets were not properly bolted. There was  $\frac{1}{2}$ -inch space between the front flue sheet and the barrel seam when sent to the bull machine for riveting.

It is time some action is taken and the Code lived up to; for it is not right to make one firm build standard boilers and another party be allowed to put slip-shod work across for it is unfair competition and an injustice.

Olean, N. Y. CHARLES W. CARTER, JR.

# Fatal Boiler Explosion Caused by Low Water

#### (Continued from page 318)

the same type and tested under steam and found in good condition.

Locomotive was equipped with four consolidated safety valves, open type, 3-inch diameter, numbers 27,644, 27,596, 27,701, and 30,998, which were removed and applied on locomotive 3,204 of the same type and tested and found to open at 182, 195, 202 and 211 pounds, respectively.

The boiler of locomotive 3,201 was washed April 14 and monthly inspection completed April 16 at Minot, N. D., and locomotive was performing first service after monthly inspection.

Left water glass tube was broken while spindles were being removed for cleaning at time boiler was washed and inspected and a new water glass applied.

The last monthly inspection of locomotive 3,201 was on April 16, 1923, at Minot, N. D.

#### DAILY INSPECTION REPORTS

Work reports for locomotive 3,201 dated March 1, 6, 8, 24, 27 and 30 and April 1, 4 and 14, which were on file at Minot, were examined, but none contained defects which in our opinion may have contributed to accident except report for April 14 on page 2, where appears notation, "Water glass" M. Donsvar, which refers to water glass which was broken out and reapplied at time glass cocks were being cleaned.

#### CONCLUSIONS FROM INVESTIGATION

Several appurtenances were damaged so that condition prior to accident could not be determined.

The general condition of the locomotive was apparently good prior to the accident.

The crown sheet failure was caused by overheating due to low water.

The only special notation in the report is that treated water is used on this division and foaming of water in boiler is a common occurrence.

# TRADE PUBLICATIONS

HYDRAULIC RIVETERS.—A four-page circular illustrating and describing Hanna hydraulic riveters has just been issued by the Hanna Engineering Company, Chicago.

WELDING CABLE.—Two announcements by the Rome Wire Company, Rome, N. Y., have been published describing special extra flexible electric welding cable and special-service cord. Many applications of these two types of cord, the first for welding outfits and the second for a variety of shop and household uses, are outlined.

HYDRAULIC MACHINERY AND POWER TOOLS.—"An Album of Engineering Achievement" is the title of a 64-page, illustrated catalogue recently issued by the Southwark Foundry & Machine Company, Philadelphia, Pa., featuring the wide application of Southwark hydraulic valves, accumulators, presses, intensifiers, power punches, etc.

WELDING AND CUTTING EQUIPMENT.—The Torchweld Equipment Company, Chicago, Ill., has issued a new catalogue covering its complete line of oxy-acetylene welding and cutting apparatus, lead welding, soldering, brazing, decarbonizing units, gas pressure regulators, automatic machines, generators and supplies. The catalogue contains cross sectional views of equipment with detailed explanations.

FLOOR AND BENCH GRINDERS.—The two-wheel floor and bench grinders, manufactured by the Hisey-Wolf Machine Company, Cincinnati, O., are illustrated and described in detail in a new bulletin prepared by the company. Floor stand grinders are made in seven sizes ranging from  $\frac{1}{2}$  to 10 horsepower capacity, while the bench grinders are in two sizes of  $\frac{1}{2}$  to 1 horsepower capacity. The special features of these grinders are outlined with specifications and other details.

CHARCOAL IRON BOILER TUBES.—A 52-page brochure, citing a few instances of the high resistance of Parkesburg charcoal iron boiler tubes to corrosion and long service life, has been issued by the Parkesburg Iron Company, Parkesburg, Pa. Following a brief outline of the physical properties of charcoal iron and its corrosion resisting qualities, is an interesting illustrated story of the Parkesburg process of manufacturing boiler tubes from the charging of the forge fire to the final inspection and test of the finished product.

BOILER FEED PUMP AND FEED WATER HEATER.—The construction and operation of the Worthington locomotive boiler feed pump and feed water heater are clearly shown in colored diagrams in an attractive 16-page bulletin, B-1607-B, recently issued by the Worthington Pump & Machinery Company, New York. The heat and coal saving characteristics of the feed water heater are shown in curves. A table of the properties of steam is also given and examples illustrating its use in calculating the reduction in the amount of heat required to generate the steam, the amount of steam required for heating and the amount of water saved by the Worthington locomotive feed water heater.

# SELECTED BOILER PATENTS

Compiled by GEORGE A. HUTCHINSON, Patent Attorney, Washington Loan and Trust Building Washington, D. C. Readers wishing copies of patent papers, or any further information regard-ing any patent described, should correspond with Mr. Hutchinson.

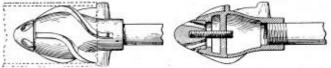

1,456,315. BOILER PLUG. FREDERICK E. KEY, OF ST. LOUIS, MISSOURI, ASSIGNOR TO KEY BOILER EQUIPMENT COMPANY, OF ST. LOUIS, MISSOURI, A CORPORATION OF MISSOURI.

Claim 1.—A device of the character described, the combination of a wall member having a circular opening providing an annular plug-receiving seat, a hollow sheet metal boiler plug closed at its inner end and open at its outer end, said boiler plug having a smooth annular conico-cylindrical peripheral portion adapted to frictionally engage said annular seat, said

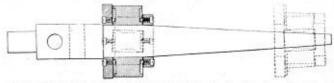

conico-cylindrical portion being so tapered as to decrease in diameter toward the open outer end of the plug so that the plug, acting like a check valve, may be forced into frictional engagement with its seat by outward pressure on its closed inner end, the annular open outer end portion of the plug being adapted to pass through and extend from said opening, and a safety device preventing accidental inward displacement of the plug from said open-ing, said safety device comprising a detachable retaining device extending entirely through the wall of the last mentioned end portion and projecting from the peripheral face thereof at a point in front of the outer face of said wall member to retain the plug in said opening. Two claims.

1,460,669. BOILER-TUBE CLEANER. JOHN H. GOODFELLOW, OF BUFFALO, NEW YORK. Claim 1.—A boiler tube cleaner comprising a hollow body, spiral flanges arranged in spaced relation on the outer face of said body, and a nozzle arranged at the front end of said body and provided with a plurality of

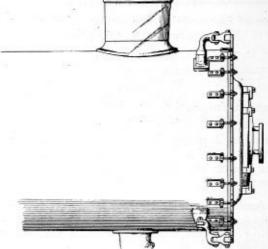

forwardly diverging jet openings for the passage of the cleaning medium therethrough, the outlet ends of said openings being flared and located in the sides of said nozzle and immediately in front of the spaces between said flanges. Five claims.

1,467,238. TUBE EXPANDER. JAMES T. DEMPSEY, OF NEW BEDFORD, MASSACHUSETTS. *Claim* 1.—A tube expander having, in combination, a head provided with a cylindrical longitudinal bore extending therethrough there being two pairs of diametrically opposed slots extending through the wall of said head, the slots of one of said pairs being positioned parallel to the axis of said bore

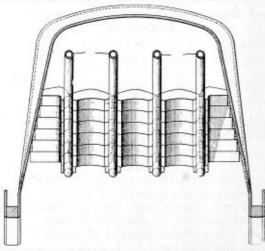

and the slots of the other of said pairs being inclined to the axis of said bore, a pair of cylindrical rolls in said parallel slots, a pair of forming rolls in said inclined slots and means projecting into said rolls from opposite ends of their respective slots and adapted to loosely position and retain said rolls in their respective slots. Two claims.

1,461,315. LOCOMOTIVE SMOKE-BOX FRONT. ARTHUR T. KUEHNER, OF ELKRILIGE, MARYLAND. Claim 1.—The combination with a lacomotive, and a smoke box from closing the smoke box of the locomotive, of a series of mating plates ex-tending around the peripheral margin of the front and forming a reinforcing

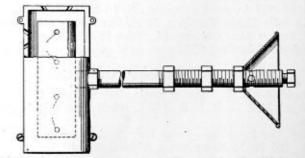

ring thereon, means coacting with certain of said plates for detachably se-curing the front in position, and means adapted to extend between the smoke box and certain other oppositely disposed plates for pivotally sup-porting the front whereby the front may be swung to one side. Five claims.

1,468,308. LOCOMOTIVE ARCH. CHARLES E. MILLER, OF CHICAGO, ILLINOIS. Claim 1.-In a locomotive arch, the combination with arch tubes and side sheets, of bricks laid upon and closing the space between adjacent tubes,

and an L-shaped brick having arms of unequal length the short arm extend-ing vertically and resting upon an outside arch tube and the long arm ex-tending horizontally and abutting a side sheet. Four claims.

1,465,502. AIR-FEEDING ATTACHMENT FOR FURNACES. HARRY W. WEAVER, OF ALLENTOWN, PENNSYLVANIA. Claim.—An air feeding device for furnace doors comprising an exter-nally threaded pipe extending through said door, the outer part of the pipe having air inlet openings in the side walls thereof, a screw plug in the outer

end of the pipe, adjustable to open or close said openings, a funnel shaped air collector screwed on the outside of the pipe, between said openings and the door, nuts on the pipe, clamping the same to the door, an outer per-forated chamber having screw threaded engagement on the pipe, inside the door, and an inner perforated chamber, also screwed on the inner end of said pipe, inside of said outer chamber.

# High Pressure Tank Used for Testing Aircraft

# By Cyrus Hankins

The story of the construction of the aeronautical testing chamber given below indicates the adaptability of the shipyard machinery to the fabrication of heavy plate structures that could not be accommodated in the ordinary tank shop. The shell plates in this tank are 2½ inches thick, the heads are made of 1¼-inch plate and the heaviest single plate weighs 15,820 pounds. The general outline of the preliminary layout and final assembly of the tank bring out a number of special methods used by the Newport News Shipbuilding and Dry Dock Company that might well be adopted on other types of heavy tank construction.

A FEW months ago work was completed by the Newport News Shipbuilding and Dry Dock Company, Newport News, Va., on a special form of wind tunnel or aircraft testing tank, detailed information for which has only recently been released for publication. This tank is used to house a wind tunnel and is capable of withstanding an internal pressure of 300 pounds per square inch.

The only information on the requirements of the tank given to the builders by the National Advisory Committee on Aeronautics were the general dimensions and the details involved in the arrangement of the wind tunnel.

The general dimensions of the tank are as follows:

Outside diameter of tank	15 feet 0 inch
Length cylindrical shell	20 feet 6 inches
Length overall	34 feet 6 inches

Working pressure per square inch	300 pounds
Test pressure per square inch	
Thickness of shell plates	21/8 inches
Thickness of hemispherical heads	11/4 inches

There is an access door in one head, 3 feet by 3 feet 6 inches clear opening, with a sight hole at the center of the door, or on the center line of the cylinder. The opposite end has provisions for a stuffing box and bearing for a propeller operated on the inside of the chamber by a shaft extending through the head of the chamber. Electrical connections and other attachments are provided as necessary.

#### MATERIALS OF CONSTRUCTION

The material used for the shell, and the plate portion of the heads was oil hardened steel, 60,000 pounds minimum

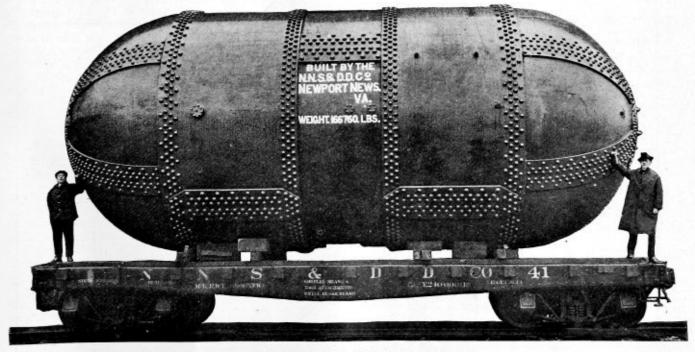

Fig. 1.-Completed Tank Ready for Shipment

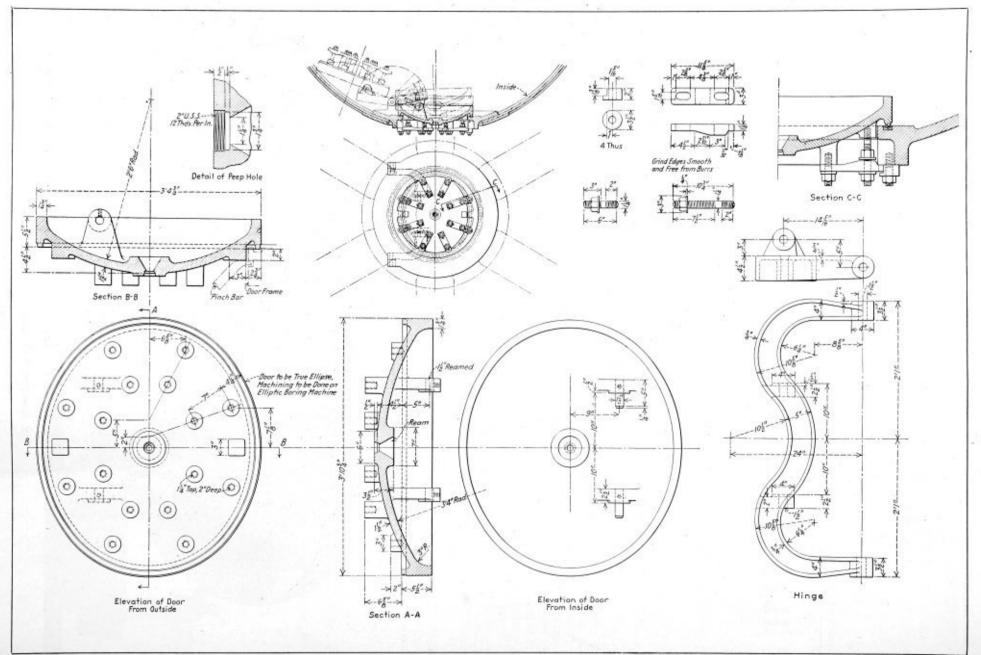

Fig. 2.-Details of Doors and Frame Castings

330

1.1

DECEMBER, 1923

tensile strength, of boiler flange quality. The heaviest single plate weighed 15,820 pounds. The rivets were made from oil hardened steel, 55,000 to 65,000 pounds tensile strength, the manufacturers furnishing certificates covering the tests.

The steel castings were made by the builders from electric furnace steel, and were of quality equivalent to United States Navy grade "B," having 60,000 pounds minimum tensile strength, with other requirements as for grade "B" castings. Test coupons were taken from all castings and subjected to all required tests.

# THE CYLINDRICAL SHELL

It was decided to make the cylindrical shell in three courses so that the heads might be identical in so far as their fit to the shell was involved. Also the bending power of the available plate rolls was a consideration. The length of courses and the location of the circumferential seams is such that the rivet pitch in the longitudinal seams, for each course, may be the same and of the proper pitch for the necessary efficiency.

The thickness of shell for the cylindrical portion was determined in the usual manner and found to be 21/8 inches. The rivets in the longitudinal seams are 134 inches diameter with 1 13/16-inch diameter holes with a pitch in the outer row of 10 3/16 inches. A triple riveted seam, rather than one with a greater number of rivets, was found desirable, as the plate efficiency could not be improved except by a greater pitch in the outer row, and a pitch of 10 3/16 inches was considered the limit for satisfactory calking of the butt straps. The large rivets of such length presented an unusual problem so experiments were conducted in driving 134-inch diameter rivets in a combined plate thickness of 51% inches which was the greatest combined thickness of shell. These plates were then cut through the rivets and it was found that they filled a 1 13/16-inch diameter hole almost perfectly in every case. Hydraulic riveting was used. butts are of equal thickness and width inside and outside.

The circumferential seams are triple riveted lap joints. The load per inch of length along the circumferential joint being only one-half that for the longitudinal joint for the same diameter, this type of joint was satisfactory. Rivets 15%-inch diameter with 1 11/16-inch diameter holes were used, it being desirable to use as small rivets as possible. The pitch of rivets in the rows is slightly less than three diameters which is the usual pitch. The total number of rivets in each row, however, was worked out to be a number divisible by four as well as six which was a laying out and assembly requirement, it being always essential to have a rivet fall on the vertical as well as the horizontal center lines and in this case the heads being made in six pieces it was also essential that the rivets in each head sector be alike, which is the necessity of being divisible by six. The stresses in the rivets and in the plate between rivets in the circumferential seam are less than those in the longitudinal seam, but are proportional.

The rolling of the plates was exactly the same as for a large Scotch boiler except for their unusual thickness. The drilling was done with a three stand special boiler shell drill. The machining of the plate edges was done on the usual type of plate planer. After drilling all plates were taken apart and rivet holes cleaned free of burrs.

The butt straps for the longitudinal seams were bent cold to the required radius between curved dies under a 200-ton hydraulic press.

The rivets for the cylindrical shell were hydraulically driven. All seams and rivets were calked in the usual manner.

# DESIGN OF THE HEMISPHERICAL HEADS

The design of the heads presented a very interesting problem. Bumped heads were found impractical, because it was impossible to secure plates of sufficient size to make them from one piece, and the different radii encountered in a bumped head would make joints in it very difficult. Cast steel heads were considered but the weight involved, and the difficulties of attaining good castings for heads of one piece, and the unsatisfactory joint that could be developed with a multiple piece head, caused this to be abandoned. A hemispherical head made of six pieces was finally adopted. The principal reasons for this shape were, that the unit load along an element of a hemisphere is only one-half that along a longitudinal element of a cylinder of the same diameter. This would result theoretically in a plate thickness of only one-half that of the cylindrical shell, provided as efficient a joint could be developed. Also this hemispherical head of at least six sectors was a shape that could be generated under dies more perfectly than any other shape.

In ordering the plates for these head sectors, an approximate development was made based on the length of great

Fig. 3 .- Head in Process of Assembly

circle arcs, taken at a series of equidistant positions and an allowance of about 21/2 inches was made on every edge. The sketch to which the plates were ordered was made in straight lines, however, no attempt being made to trim plates in ordering or before bumping to their final shape. Two small scale plates, about 3/3 scale for all dimensions, were bumped between dies of the same scale and a study made of the behavior of these plates in being shaped. One sample was bumped from the flat, and the other rolled longitudinally to the desired radius and then worked between the dies. Great circles were then layed off on these small plates and the lengths of the arcs measured to determine the behavior of the plate, it was found that there was practically no stretching in any part of the material, the greatest longitudinal length being only about 1/4 inch greater than before bumping. But there was shown to be a decided contraction in the width as measured on great circle arcs. This contraction was such in these 3/5 scale models, that should it be proportional in the full size plate it would take at least half of the 21/2-inch allowance given in ordering. This proved true in bumping the full size plates.

The thickness of the head plates was made 134 inches, which was 3/16 inch in excess of the theoretical thickness, to have the same stress as in the shell with an equally efficient seam. This excess was given to cover unknown factors that might result from furnace work and local heating. The inner and outer butt straps, as well as the circular butt strap adjacent to the head end castings, were formed to spherical surfaces of the proper radius for their respective positions. A liberal excess was allowed in the ordered width of the butt

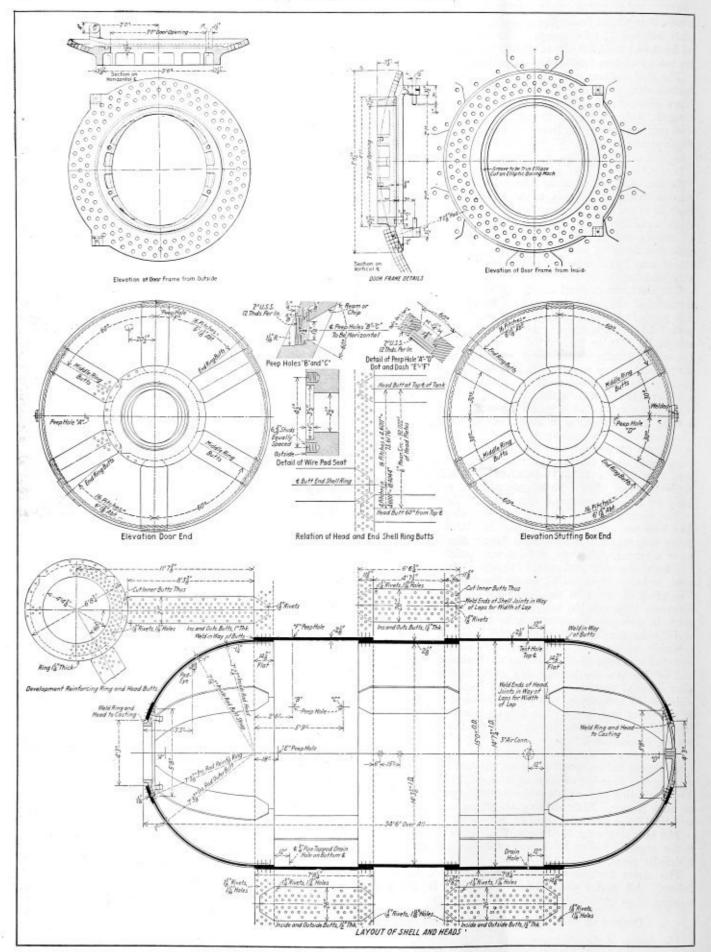

Fig. 4.-Layout of Shell and Heads for Testing Chamber

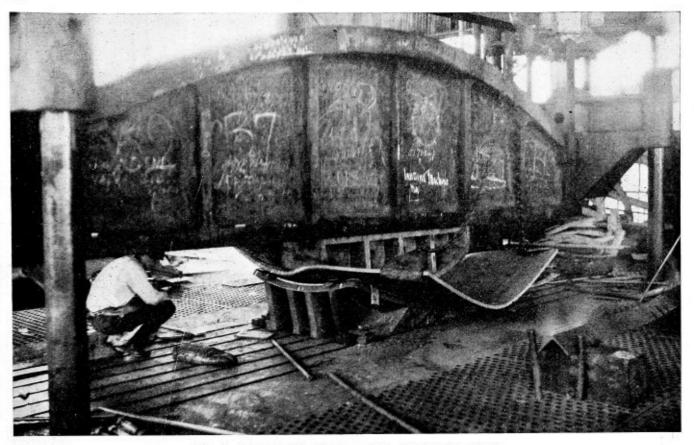

Fig. 5.-Bumping One Section of the Air Chamber Head

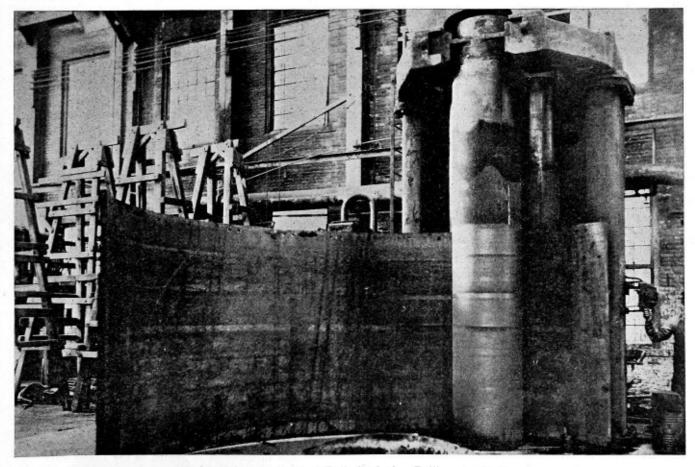

Fig. 6.-Heavy Vertical Rolls in Action Rolling the Shell

straps to provide for a possible wind in their length in being formed, which excess was found desirable on some plates, while others remained practically straight along their edges.

For generating these spherical head sectors and butt straps, upper and lower dies with spherical surfaces corresponding to the inside and outside radii of the head plates were used. The lower die was about 7 feet by 7 feet, being made like a basin with its inner surface corresponding to the outer surface of the head. The upper die was about 7 feet long by 2 feet wide and had its outer surface corresponding to the inner radius of the head. These dies were fitted in a 600 ton hydraulic press.

The plate was brought to a light red heat in a nearby furnace, then handled by crane to the edge of the lower die. The narrow end of the plate being inserted between the dies first, the plate was passed by successive steps of about 2 feet between the dies. After forming the entire plate at one heat, as was done, the plate was worked between the dies in numerous small, or smoothing out, impressions. This operation tended to remove any distortions that the already spherically formed portion of the plate may have suffered. On fully cooling it was found that there had been a very slight shrinkage, with reductions in all directions, including the radius. This change in the desired radius was corrected, being at maximum only about 3% inch in a 7-foot 25%-inch radius, by putting the plates through the dies cold and subjecting them to numerous impressions of the upper die.

The forming of the butt straps and the circular butt at the end of head was identical with the forming of the head plates. The dies were shimmed to suit the varying radii, made necessary by the difference in the inner and outer butt straps.

The laying out of the head sectors for assembling, was accomplished by the use of a wooden templet made to the inner radius of the head and for 1/6 of the head. This templet included the 147%-inch portion that was to form the lap of the head with the cylindrical shell. This portion being formed spherically along with the rest of the head sector for sake of ease of manipulation between dies, and was pulled back to a cylinder after assembly of heads. This templet was laid in each formed plate and scribed around.

Six head sectors after chipping were set up to form a complete head, any high spots resulting from chipping were marked, and the sectors match marked, then taken down and all high spots chipped so that the head assembled with exactly the desired circumference.

The heads were fitted on the ends with castings in general already described. The door frame casting was designed with the addition of the 1¼-inch circular butt to compensate for the cut away portion of the hemispherical head plate.

The door opening, in the door frame casting, as well as the door were made elliptical to allow the door to be inserted or withdrawn at any time.

The machining of the packing groove and contacting face of door are to a perfect ellipse, being generated on an elliptic boring mill. All other machining on these castings was done in the usual manner.

The packing used in the packing groove is Johns-Manville, Kearsarge, Style No. 1761/2, made continuous to special order to suit the groove. The load on this packing at 300 pounds per square inch working pressure is approximately 3,400 pounds per inch of length.

The door was designed for relatively low stresses, to Bach's theory for stresses in structures supported at their periphery and uinformly loaded and checked by methods used for figuring stresses in steam turbine diaphragms and other similar structures. The door is provided with eight dogs, capable of exerting a pressure on the gasket equal to about one-half that exerted by the working pressure, which was considered ample to compress the gasket sufficiently to overcome leakage at low pressures. The door weighs approximately 1,500 pounds. The door hinge owes its peculiar shape to the necessity of being able to move the door inwardly with practically parallel movement until it has reached a point at which the dogs are clear of the door frame. Also the hinge is bent backward at the center to clear the line of vision from the peep hole at the center of the door.

The castings were all made as simple and rugged as possible to facilitate foundry work, machining, assembly, and with the view to keeping down secondary stresses as far as possible.

The assembly of the heads to the shell differed little from a large Scotch boiler, the door, hinge, and other castings offered no difficulty, being machined to fit.

The test was by hydraulic pressure of one and one-half times the maximum working pressure, or 450 pounds per square inch.

Welding was extensively used to secure all seams and butt strap ends, not readily accessible for calking.

# Opportunity for American Manufacturers to Exhibit Products in Europe

THE fair held at Lyons, France, each year is by far the most important annual exposition in Europe. The next meeting of this fair in Lyons will be from March 3 to

17, 1924.

An opportunity is available through the official delegate of the Lyons fair for the United States for American manufacturers, especially those who specialize in labor-saving devices and machinery to exhibit at the coming exposition. Those manufacturers who cannot spare the time and expense of attending the meeting personally can join the all-American demonstration and trade exhibit now being organized here.

The Lyons Fair is the most important commercial and industrial manifestation today on the continent of Europe. This fact will be better understood when it is stated that, at the 1923 meeting of the Lyons Fair, local records have shown the number of actual buyers to be over 160,000, while the total number of visitors exceeded 400,000.

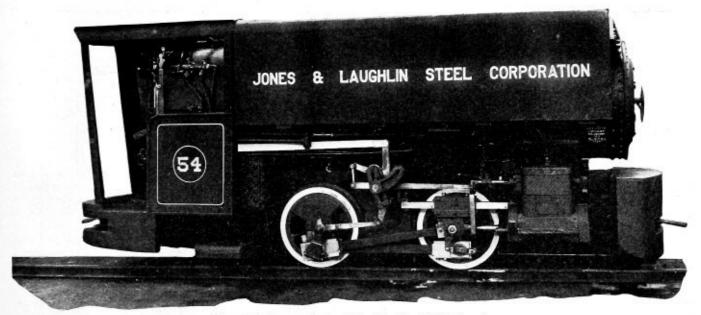

The Lyons Fair is not a mere show intended to attract crowds of visitors. It is first and foremost a sample Fair, that is a business Fair in the fullest meaning of the word. The main purpose of this institution is to develop trade, to facilitate transactions, to bring the producer or manufacturer and their products to prospective buyers. Everything else has been made subservient to this purpose. The booths provided constitute real business offices where business men can get together and discuss their transactions with the utmost comfort and privacy with as much ease as they would in their home office or factory.

The Palace of the Lyons Fair, which will be completed in the near future, will be one of the most prominent attractions of Europe, where it is already considered a marvel of architecture, convenience and size. It will extend over threequarters of a mile. Twenty pavilions will be ready in the spring of 1924, the whole constituting a unique business city such as can be found today in no other country.

M. Herriot, the mayor of Lyons, came recently to the United States for the purpose of calling the Lyons Fair and its business opportunities to the attention of American manufacturers and to invite them to come in great numbers to the next meeting of the Fair (March 3 to 17, 1924).

Similar visits made by M. Herriot in the last few years to England, Switzerland and even Russia proved highly successful and have made the Lyons Fair one of the greatest international events in the world of business.

For full information in regard to the Lyons Fair, apply to Emile Garden, Official Delegate for the United States and Canada, 50 Church Street, New York.

Compact, Heavy Locomotive for Steel Mill Service

# Small Heavy Locomotives Built for Mill Service

Extra Heavy Plate Used in Boiler and Throughout Structure to Bring Locomotives to Required Weight

# By C. E. Lester

Some rather unique locomotives recently built for the Jones and Laughlin Steel Corporation are illustrated in the accompanying drawing and photograph and briefly described in the following paragraphs; the features of the design lying principally in the great weight carried on a short wheel base and narrow gage track.

There were many limiting factors entering into the design that, in a measure, prohibited the following out of generally accepted principles of locomotive construction and caused a departure from such principles, or rather some modifications of ratios, etc.

Due to mill conditions for clearance, the overall height was limited to 7 feet 3 inches and the width to 4 feet 10 inches over a gage of 23 inches. The curvature of the track required a wheel base of not over 48 inches and with heavy duty and an extremely slippery rail weight of about 60,000 pounds was desired for adhesion. The extreme length over bumpers is 17 feet, yet the load on the track is distributed over the very small area of 1,104 square inches or about 54 pounds per square inch of track area. These locomotives are operated over a railroad constructed of 120 pound rails and steel cross ties.

#### EXTREME WEIGHT FOR SIZE OF LOCOMOTIVE

This weight on a locomotive of this size where the weight would normally be about 40,000 pounds, required the addition of weight wherever possible, without interference with the working parts. The needed excess weight was added in many places, having in view the necessity of correct distribution and the desire for symmetrical lines. For example, the saddle tank weighs about 6,500 pounds, the boiler front is of double thickness, as is also the smoke stack; the steam chests and cylinders are massively built; the frames are of slab construction 3 inches thick with practically no cut outs except for the journal boxes and as required for the cylinders, firebox, etc.

Walschaert valve gear has been used, which places the moving parts where they can be easily oiled and cared for, while at the same time these parts are fully protected from accident by heavy castings at front and rear. Stephenson link motion had previously been used on this class of locomotives, but with such a narrow gage and large driving boxes as well as crowded conditions, the Walschaert gear is decidedly to be preferred.

It will be observed that the front and rear cast steel bumpers are of great weight and hang closely to the rail. These perform their normal functions as well as provide weight and act as buffers for foreign obstructions along the tracks.

The steel castings bolted to either side of the frames under the firebox have dual functions. They act as buffers to prevent possible injury to the valve gear and rods, while the engines are in reverse motion; provide weight and at the same time bring the center of gravity to a point where the weight is equally distributed over both driving wheels.

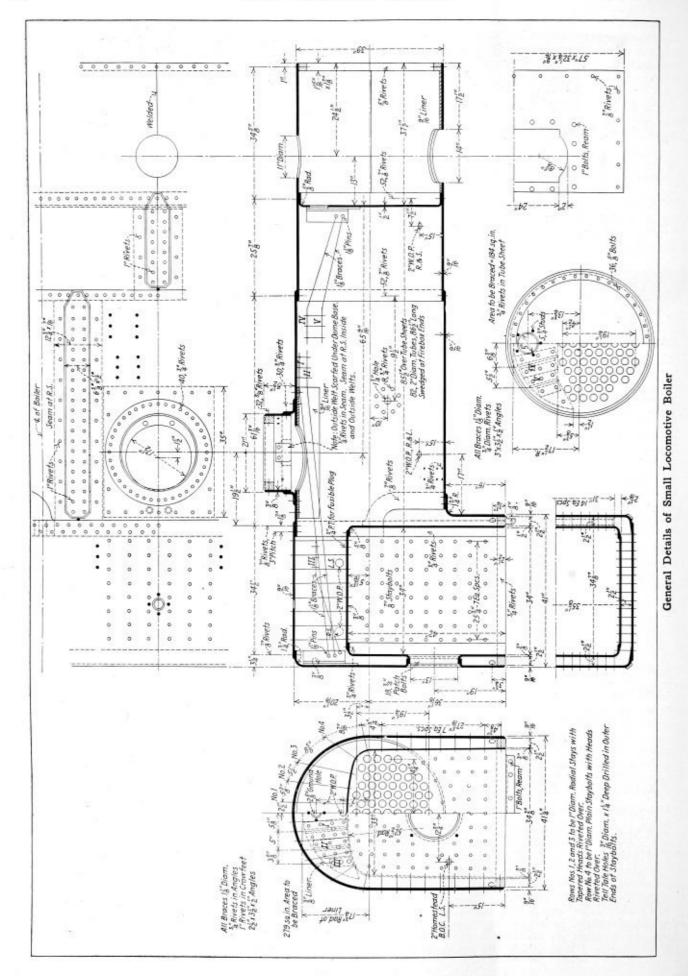

#### TYPE OF BOILER USED

Of the boiler but little may be said of the specific construction only that for purpose of weight, the plate and rivets were increased in size. For boilers of this size and pressure ordinarily 3%-inch plate and 3/4-inch rivets are used. In this case 9/16-inch plate was used in the shell and wagon top with 1-inch rivets in the horizontal seams. Incidentally the construction of the shell would permit of a working pressure of 280 pounds at a factor of safety of 5. However, the working pressure is set at 180 pounds, as the firebox is of normal construction and the additional metal in the shell was added for weight only.

The company's usual practice was followed out in using

the Porter injector check flange. This flange permits the setting of the water supply opening in the boiler either above or below the center line of the boiler, with the opening in the flange at right angles to the center line and with a full allowance of thread. One size flange may be used on boilers of various diameters.

In order to secure a maximum number of full threads in the washout holes at the mudring corners, the holes are drilled  $\frac{1}{2}$  inch small and rolled out with a special roller which thickens the plate at least 25 percent at the edge of the hole.

The boilers were built to the A. S. M. E. locomotive code, and have all mudring corners autogenously welded. The cylinders are 11 inches by 14 inches, and driving wheels are 25 inches in diameter.

No wood whatsoever was used anywhere on the locomotives, the cab and fixtures all being of metal. Due to the necessity for conservation of space the cab is small, all fixtures and moving parts closely placed and the area for the engineer somewhat confined.

Due to heat radiation from the boiler and the operation of the locomotives in close proximity to hot ingots and hot ingot molds the temperature of the water carried in the saddle tank varies in temperature from 100 degrees F. to 140 degrees F., a preheater, so to speak.

Coal is used for fuel, it is carried in an ingot car attached to the back end of the locomotive.

# Conserving the Eyesight of Industrial Workers

***E** YE Hazards in Industrial Occupations," widely known as Publication No. 12 of the National Committee for the Prevention of Blindness, first issued in 1917,, has been revised, greatly enlarged, widened in its scope, brought up to date and will be ready for distribution about January first, Lewis H. Carris, Managing Director of the Committee, announces.

The bulletin, which has been out of print since 1921, will combine in its revised form all the available information on the subject of eye hazards in industrial occupations. The field research work on the revised edition, which has been carried out under the direction of Mr. Carris, will contain the most comprehensive statistics on eye accidents available. Cooperating with the Committee in the revision of the bulletin were: the National Safety Council, the Safety Institute of America, the American Society of Safety Engineers and leading ophthalmologists.

The volume will be distributed to heads of departments of industrial plants, to engineering colleges and technical schools, and all others interested in accident prevention and health promotion among industrial workers.

There will be twelve chapters in the revised bulletin dividing the contents as follows:

Chapter I, the Introduction, will give a brief résumé of eye hazards in industry and of the safety movement, especially as it relates to the prevention of eye accidents, will discuss the proper point of view toward these hazards, emphasizing the need of physical examination of employees and pointing out that elimination of eye hazards is not only a moral obligation but good business. It will also state the place of the National Committee for the Prevention of Blindness in the general movement for the conservation of the vision of industrial workers.

Chapter II—The Nature and Causes of Eye Injuries discusses where and how eye accidents happen, and gives detailed data regarding eye injuries in various industries.

detailed data regarding eye injuries in various industries. Chapter III, devoted to the Eliminating Eye Hazards by Engineering Revision, emphasizes the importance of this newest phase of accident prevention work and describes sev-

eral typical instances of engineering revision which eliminated hazards and improved the process.

Chapter IV, entitled Industrial Accidents and Safeguards, will take up in detail, hazards and protective methods, all processes where protection is required from large flying objects, from small flying particles, from dust and wind, from splashing metal, from gases, fumes and liquids, from reflected light or glare, from injurious radiant energy, etc.

Chapter V is devoted to First Aid Treatment for Eye Injuries.

Chapter VI, entitled Correction of Defective Vision, will discuss the condition of eyesight found in the physical examinations of large numbers of working men and women and a description of the experiences of large employers such as the United States Steel Corporation.

Chapter VII will enumerate the various industrial diseases affecting the eyes and will present the most effective methods of protection against these diseases.

Chapter VIII, devoted to Eye Diseases emanating outside of industry, will discuss, among other diseases, trachoma and the responsibility of industry to help eliminate it, means of its detection, and preventatives.

Chapter IX describes Industrial Lighting, including lighting codes, artificial lighting, natural lighting and glare.

Chapter X, devoted to the Safety Movement, discusses the contribution to the movement for the elimination of the eye hazards of industry which have been made by the National Safety Council, the Safety Institute of America, American Society of Safety Engineers, Underwriters' Laboratories, local organizations devoted to safety, and the various state industrial commissions.

Chapter XI, headed Education as to Safety, is subdivided into the education of the employer, of the employe and of the State. It cites statistics to show that it is cheaper to prevent accidents than to pay for them, takes up the pros and the cons of gogglewearing, outlines a complete eye protection campaign, presents the best known means of inducing so-called hard-boiled workmen to wear goggles and discusses the moral and economic obligation of the state in safety education.

Chapter XII is devoted to the National Committee for the Prevention of Blindness and its work during the past ten years.

# Exhaust Steam Injectors

OR several years past the exhaust steam injector has been used successfully in this country for locomotive boiler feeding, but in the United States such appliances have not until recently been given much attention. At the present time the International Railway Fuel Association is investigating the subject, and the conclusion has been arrived at that, although there is not quite so great a range with the exhaust steam injector as one using live steam, the range is sufficiently great to meet the requirements of average service under American locomotive conditions. It is pointed out that locomotives and trains on British railways, which use the exhaust steam injector extensively, are not so heavy as those in the States, but since the performance of the device is considered quite satisfactory, it seems reasonable to expect successful results under the heavier conditions of serv-Tests already carried out in America with the form ice. of injector mentioned have shown coal savings from 10 to about 15 percent, the best results, as a matter of course, being obtained when the exhaust injector was kept continually at work from one end of the line to the other. Some of the most advanced and efficient locomotives on British railways are fitted with exhaust steam injectors, and we are accustomed to hear the device spoken of by those responsible for the working of the engines in terms of appreciation .- The Railway Gazette (London, England).

# Government Inspectors Report—

Two Locomotive Boiler Explosions Caused by Blown Flue Pockets and Low Water Crown Sheet Failure

HICAGO, Rock Island & Pacific Railway locomotive 2132 was dispatched from Shawnee, Okla., at 6 A. M. on July 3. 1923, in freight service. and when at a point about 2 miles west of Harrah, Okla., or 20 miles from Shawnee, and while running at an estimated speed of 20 miles per hour, a flue pocket blew out of the front flue sheet, when the escaping steam and water from the boiler caused the flames and firebox gases to be blown back into the cab, resulting in the serious inBy A. G. Pack*

A great degree of interest has been shown by our readers in the locomotive accident reports which from time to time appear in the pages of THE BOILER MAKER through the courtesy of the Bureau of Locomotive Inspection. For this reason we are outlining below two disasters both fatal which once more bring home to those men having to do with boiler maintenance and repair that the lives of many fellow human beings depend on the conscientious manner in which they do their work.

The Bureau of Locomotive Inspection has seriously objected since its inauguration to flue pockets being applied in the firebox flue sheet because of unsafe conditions created. It has not, however, objected to flue pockets applied in reasonable number in the front flue sheet when properly belled and prossered, but we do not approve as being proper and safe practice of applying the number of flue pockets which were found in this instance, for the reason that it leaves a large unsupported area

jury of the engineer and the fireman who was with him. This locomotive was turned out of the Shawnee shops of this carrier on July 1, or two days prior to the accident, after having received class 3 repairs and was at the time of the accident making its first regular trip in freight service since receiving repairs. During the repairs all flues were renewed and 40 flue pockets, which had been previously applied, were renewed and 8 additional flue pockets were applied, making a total of 48 flue pockets applied in the front flue sheet for the purpose of closing holes from which flues had been removed when changes in the firebox sheet were made.

### EXAMINATION OF FLUE POCKET

Examination disclosed that neither the flue pocket which blew out, as illustrated in Fig. 1, nor any of the others, had been prossered, but were only held in place by friction.

The flue pockets were applied by a boilermaker helper and were inspected by the company boiler inspector, who signed and swore to the annual locomotive inspection and repair report, dated July 1, 1923, showing that all flues were in good condition. The report was approved by the general foreman, as officer in charge.

Our examination of locomotives Nos. 2120, 2135, 2139 and 2144 disclosed that in each of the front flue sheets there were 48 flue pockets which had not been prossered, or means provided to secure them in place, other than friction. The carrier's records show that all of these locomotives received new flues and flue pockets during the period January to April, 1923.

Fig. 1 shows the flue pocket as applied and held only by friction, while Fig. 2 shows the manner in which the flue pocket should have been prossered or enlarged inside of the flue sheet, which would have prevented it from blowing out.

The necessity for properly prossering or enlarging flue pockets inside the sheet is so well recognized by mechanics that comment hardly seems necessary. The workmen who did this work and the supervising officials in charge who permitted it cannot be too strongly censured for such careless and indifferent methods, which show an extreme disregard for safety on their part. and throws an undue strain on the remaining adjacent flues.

#### CROWN SHEET FAILURE

On August 19, 1923, the boiler of New York, New Haven & Hartford locomotive 409 exploded, resulting in the fatal injury of the engineer and serious injury to the fireman and two passengers.

This locomotive left Providence, R. I., at 3:00 P. M., August 19, hauling passenger train No. 3344, consisting of two coaches and a combination car. The train had proceeded to a point about one-half mile from Walpole Heights, or a distance of about twenty-five miles from Providence, when at 3:59 P. M. the boiler exploded, resulting in the fatal injury of the engineer, who died 10 days later, and the serious injury of the fireman and two passengers. The engineer and the fireman were thrown by the force of the explosion from the locomotive and were found in the river alongside the track.

Locomotive 409 was a 2-6-0, or ten-wheel type, equipped with extended wagon top boiler having a narrow radial stayed firebox. The force of the explosion tore the boiler from the frame and running gear, hurling it a distance of approximately 300 feet, where it struck the ground and rebounded, and came to rest about 350 feet ahead from the point of explosion.

### FIREBOX CONSTRUCTION

The firebox was originally of five-piece construction, consisting of flue sheet  $\frac{1}{2}$  inch thick, and 2 side sheets, crown and door sheets  $\frac{3}{8}$  inch thick. The crown sheet was supported by 16 longitudinal rows and 28 transverse rows of stays, of which the 6 center rows were of the button-head type, excepting the first 2 transverse rows back of the flue sheet and the first transverse row in front of the door sheet were hammered heads. The crown stays were  $1\frac{1}{4}$  inches in diameter at the threaded ends, with bodies reduced to 1 inch diameter, spaced  $3\frac{3}{4}$  by  $3\frac{3}{4}$  inches. The staybolts varied in diameter from 1 inch to  $1\frac{1}{8}$  inches, and were spaced  $3\frac{3}{4}$  by  $3\frac{3}{4}$  inches.

The firebox had been patched as follows, with seams autogenously welded, which showed that the metal had not properly fused:

*Chief Inspector, Bureau of Locomotive Inspection.

338

One patch between the eleventh and twelfth rows of stays each side of the center line of the crown sheet, extending from the eighth to the seventeenth staybolt, counting from the flue sheet.

Two patches, one on each side, running full length of the firebox between the fourteenth and fifteenth longitudinal rows of staybolts, counting from the center line of the crown sheet.

Door sheet had been welded to side sheets for a distance of 44 inches up from mud ring.

Welded seam across the entire width of door sheet 21¹/₂ inches below top of crown sheet.

The top portion of the door sheet was riveted to the crown sheet, while the flue sheet was welded to both the crown and side sheets.

EXAMINATION OF FIREBOX AFTER ACCIDENT

Investigation disclosed that the crown sheet had been overheated, due to low water from the flue sheet to the door sheet, extending between the seventh and eighth rows of stays on each side of center at the front and between fourth and fifth rows on each side at the back end. Many of the crown stay holes were elongated, in some instances as much

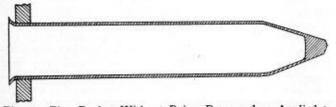

Fig. 1.—Flue Pocket Without Being Prossered as Applied to Locomotive 2132 and Others

as 1 inch, and the crown sheet stretched to a thickness of approximately 1/8 inch in places where it tore.

The crown sheet pulled away from 298 stays and ruptured; the initial rupture apparently beginning at the

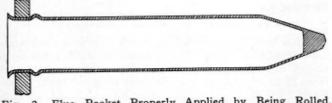

Fig. 2.—Flue Pocket Properly Applied by Being Rolled, Belled and Prossered

welded flue sheet seam near the center line of the crown sheet and followed this seam, which was very defective, down to the welded seam on the right side sheet, which seam failed for a distance of  $26\frac{1}{4}$  inches through the weld, then through the solid plate for a distance of  $11\frac{1}{2}$  inches, then through the welded seam for a distance of 33 inches, then through the welded seam for a distance of  $13\frac{1}{2}$  inches, or to the door sheet. The fifth sling stay on the right side in the first transverse row was missing and showed an old break at the wrapper sheet. The ninth and tenth stays adjacent on the right side in the first transverse row, thirteenth stay from the flue sheet in the sixth row, and the twentyseventh stay in the ninth row were broken with old breaks, making a total of 5 broken crown stays and 1 broken sling stay.

Considering that the ninth and tenth adjacent stays were broken, and the defective condition of the welded seam, and the manner in which the sheets tore, it is evident that the initial rupture occurred in this seam and that the violence of the explosion was increased by the failure of the welded seam. Water Glass. The boiler was equipped with an Ashcroft prismatic water glass, the bottom stem of which was bent and the top stem broken off at the frame—free from scale and sediment.

Gage Cocks. The boiler was equipped with three gage cocks, screwed in the back head, near the knuckle, which were broken off at the time of the accident, one of which was not found. The two which were found were free from scale and sediment.

The left injector, right check valve, and steam gage were badly damaged and their condition prior to the accident could not be determined. The right injector, left check valve, safety valves, tank and tank wells were in good condition. Right tank hose was in good condition except that strainer was missing, and the left tank hose was missing.

#### DAILY LOCOMOTIVE INSPECTION REPORTS

Daily locomotive inspection reports were examined covering the period August 1 to August 18, the date prior to the accident, and the following conditions found reported at Southampton Enginehouse, Boston, Mass.

- August 1, 1923, 8:40 A. M.—Side sheet leaking right side, staybolts leaking around thread. Not serious enough to dump engine.
- August 10, 1923, 8:30 A. M.—Leaking around firebox door. Side sheet leaking right side. Engine dumped. Staybolts hammered, leak in fire door calked.
- August 11, 1923, 8:30 A. M.—Side sheet leaking right side, leaking around firebox door. Staybolts leaking around thread. Not serious enough to dump engine.
- August 11, 1923, 1:10 P. M.—Side sheets and staybolts leaking in firebox. Staybolt leaking around thread, not serious enough to dump engine.
- August 14, 1923, 8:45 A. M.—Side sheets leaking both sides. Leaking around firebox door bad. Engine dumped. Staybolts headed over and hammered. Leak around firebox door calked.
- August 15, 1923, 8:45 A. M.—Leaking around firebox door bad. Side sheet leaking left side. Boiler check sticking right side. Firebox not leaking bad enough to dump engine.
- August 16, 1923, 8:45 A. M.—Leaking bad around firebox door. Side sheet leaking left side. Boiler check sticking right side. Engine dumped. Leak around firebox door calked. Staybolts hammered.
- August 17, 1923, 8:35 A. M.—Side sheet leaking right side. Engine not dumped. Staybolts leaking around thread. Not serious enough to dump engine.
- August 18, 1923, 9:15 A. M.—Leaking around firebox door. Engine not dumped. Leak calked.

#### CLASSIFIED REPAIRS

This locomotive received class 3 repairs at the Readville shops during the month of May, 1922, at which time the following boiler work is shown to have been done:

One-half door sheet renewed and welded on top and both sides.

- Seams on both side sheets patched, right 5 inches by 44 inches and left 5 inches by 48 inches. Patches welded on bottom and ends.
- Both sides of back head patched, right  $5\frac{1}{2}$  by 29 inches and left  $5\frac{1}{2}$  by 25 inches.
- Cracked welding on both corners on back flue sheet repaired by electric welding.

Notwithstanding the defective condition of the firebox, as indicated by the repairs made and the defective conditions evidenced by the daily locomotive inspection reports from August 1 to 18, inclusive, we have on file a sworn annual locomotive inspection and repair report, dated at (Continued on page 355)

# Saving Boiler Tubes by Treating the Feedwater*

# Experience of Several Roads with Various Methods of Softening Water in Hard Water Districts

THE Kansas City Southern, traversing a territory from the Missouri river to the Gulf of Mexico, has experienced a water condition, encountered on only a few other roads, which has been the cause of excessive boiler maintenance costs on the first district and the terminal division where all engines are furnished water from the Missouri river. This water contains from eight to 30 grains of incrusting solids to the gallon, depending on the stage of the river.

During the low water stage of the river when the water was very hard most damage was done to boilers, due to corrosion and pitting and frequent failures from leaking and bursted flues, required renewals of these parts.

In November, 1921, water treating plants were put into operation at both terminals and five intermediate water stations on the first district and the handling of all plants turned over to the mechanical engineer, who assigned a chemist to look after the proper handling of each station, analyzing each water and prescribing the proper amount of chemicals necessary. Owing to the frequent changing of the water in streams where water is obtained, it is the practice to make analysis of the water, both before and after treatment, at least once a week, and change the amount of chemicals to meet the requirements.

The pumper or water tender was instructed as to the proper methods of handling each plant, such instructions being strictly complied with and the water situation successfully handled for a period of 10 months when failures began to develop from foaming. Each failure reported was investigated and in each case found to be the result of improper treatment of the water at one or more plants or because the boiler had not been washed. Numerous cases of foaming during this period from September 1, 1922, to April 1, 1923, caused by soap, red cup grease, lye, washing powder and other foam producing substances put into water cisterns of locomotives during the shopmen's strike, were charged in some cases to the water treatment.

During the low water stage of the Missouri river the first part of this year when the total hardness was as high as 30 grains to the gallon, it was necessary to use excessive quantities of chemicals to reduce this hardness to four or five grains. This made the water so light that foaming ensued on engines engaged in heavy service. During such periods anti-foam compound in quantities of one pint to each 4,000 gallons of water is used, which eliminates the foaming difficulties and permits of efficient and economical locomotive operation.

#### DECREASE IN FLUE LEAKAGE

During the shopmen's strike beginning July 1, 1922, we experienced very little boiler or flue leakage on locomotives operating with the above treated water and very good results and improved engine performance was made possible on the second district where locomotives only received approximately 20 percent treated water.

Flues removed from locomotive boilers operating on the treated water district are not altogether free from scale, as the locomotive was either in service before the advent of feed water treatment or was sometimes run for several trips at a time over other territory where treated water is not available.

The old practice of blowing out large quantities of water at each water station has been discontinued, and instead the

*Report read at thirty-first annual convention of Traveling Engineers' Association, Chicago, September 11 to 14.

blow-off cocks are operated for a few seconds at frequent intervals, thus releasing the accumulated sludge adjacent to blow-off cocks.

In the Red river country of Arkansas, Louisiana and Texas the water contains such quantities of hardness that heavy formation of scale and pitting prevails. Compound is being used to avoid scale formation with very satisfactory results. When excessive quantities of anti-scale compound are used, sometimes foaming results, and to avoid foaming each locomotive is furnished a supply of anti-foaming compound for use only in case of foaming.

#### TROUBLE FROM FOAMING

In a salt water territory where water contains from 45 to 65 grains of salt, trouble is experienced from foaming on an evaporation of 4,000 gallons of water with boiler of approximately 3,200 gallons capacity. The foaming tendency develops on a salt concentration of 100 grains and the locomotive becomes almost inoperative on a concentration of 175 grains. This difficulty is readily overcome by the use of antifoam compound. The boiler is blown out well every four hours, water changed on four days' performance and washed after each seven days' run. The water consumption averages 870 gallons per hour, the boiler blow-out releasing about 400 gallons on each 4,400 gallons' performance, water changed on 28,000 gallons and boiler washed on an evaporation performance of 48,000 to 50,000 gallons. Under this method of handling, locomotives are operated successfully. The evaporation between wash-outs could be increased by the greater use of blow-off cocks, but the additional cost due to waste of fuel would more than offset the cost of wash-outs and fuel for firing up.

# BOILER WASHING PERIOD LENGTHENED

In has been the past practice to wash boilers on a calendarday instead of on evaporation performance, which is not satisfactory in pooled engine service, as locomotives often work from 12 to 20 hours per day in times of heavy traffic movements. In one locality boiler foaming was found, presumably on account of using a certain boiler compound, but upon investigation it was found that the engines were being run far beyond the limit possible on account of the high concentration. The past practice was to wash the boilers every seven days. These engines, however, worked from 12 to 20 hours a day in pooled service instead of eight hours a day on former regular assignment, therefore the evaporation between wash-out had been increased from 50,000 (where the concentration was great enough to justify wash-outs) to over 110,000 gallons, when excessive foaming developed, making economical and efficient locomotive operation an impossibility.

This difficulty has been overcome by adopting a boiler wash-out board to be handled by the engine dispatcher or enginehouse clerk who marks up the board every trip the engine makes, and when it has made the desired number of hours or miles the boiler is washed out.

On the Chicago division of the Pere Marquette, between Grand Rapids, Mich., and Chicago, and also on the subdivision between Holland, Mich., and Pentwater, boiler chemicals are in use, while on the territory between Toledo, Ohio, and Saginaw, Mich., another compound is being tested.

#### WATER SOFTENING COMPOUNDS

One of these compounds is made up in one-pound sticks, and is applied by placing from 8 to 16 pounds (according to size of boiler) into the several different wash-out holes in the boiler after the boiler has been washed. This compound, among other ingredients, contains treated mercury, which attacks the scale that has already formed on the bolts, tubes and sheets, breaking it loose. The scale does not all drop off, but is loosened and will turn on the bolts and braces similar to a bushing. Most of it is dislodged and washed out at the following wash-out period. Great care is necessary in washing the boilers that are heavy with scale before applying this treatment, as large quantities of scale will be dislodged and accumulated. This will inevitably result in mud burned sheets.

The other compound is made up in one-pound round balls and is applied by placing the required number of balls in a container, which is attached to the intake pipe of the wayside tank. An analysis of the water is taken in order to determine the amount of compound that is necessary to neutralize the water at any particular tank. The chemical acts by attacking and precipitating the scale-forming solids in the water before it reaches the locomotive tank, thereby prohibiting, to a large extent, the formation of scale. It is handled by the maintenance of way men, a specified number of balls of compound being placed in the container every 24 hours, according to the analysis of the water.

Practically no trouble is experienced with engines foaming or boilers pitting. The problem is to keep boiler tubes, bolts and sheets from being insulated with scale. The scale is of the carbon magnesia type, and before using any water treatment it was not uncommon to find the tubes, bolts and sheets insulated with scale  $\frac{3}{8}$  inch to  $\frac{1}{2}$  inch in thickness. In some instances scale formation exceeded these dimensions. While the boiler compound has not entirely eliminated the formation of scale, it has greatly reduced the thickness of scale insulation. It is a rare instance to find over 1/16 inch to  $\frac{3}{32}$  inch scale on engines running in territories where boiler compound is in use. Where formerly it was necessary to reduce nozzles as scale formation increased, a standard size nozzle is now maintained. Engines that were formerly run with 6-inch nozzles are now running with 6 $\frac{1}{4}$ -inch nozzles. This has not only reduced the fuel consumption of our locomotives, but has increased their efficiency, due to the decreased back pressure.

There are nine less hot workers employed at Saginaw and Wyoming than formerly; this alone has resulted in a saving of approximately \$50 per day or a total of \$18,250 per year. At the power plant at Saginaw shops there is a battery of four 250-horsepower Wickes type boilers. It formerly took two men 18 hours to thoroughly wash and turbine each of these boilers, which were washed once every 30 days. This is now being handled by the same number of men in an eight-hour period, and the wash-out has been extended from 30 to 60 days, resulting in an annual saving of \$658.56. The period between wash-outs has not been increased on locomotives, the practice being to wash engines every 10 days.

The report was signed by T. H. Clapham (K. C. S.), chairman; G. M. Basford (Lima Locomotive Works, Inc.), C. F. Willoughly (P. M.), J. H. Alter (N. Y. C. & St. L.) and J. H. Cooper (Dearborn Chemical Co.).

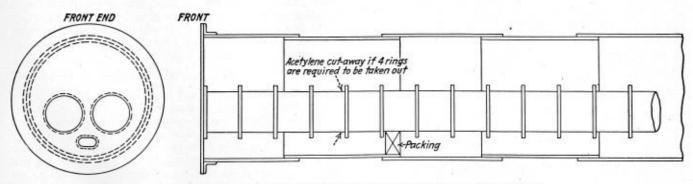

# Renewing Flue Rings in Lancashire Boilers

# British Practice of Withdrawing Tubes, Cutting Away Defective Flue Ring and Assembling New Ring

### By H. Holmes

T is the universal practice in England when renewal of one, two, three or four defective firebox flue rings is necessary, to take off the front end plate of the boiler, also to take the rivets out of the flues adjoining the back end plates so as to release the flues for drawing out of the shell of the in the renewal of several flue units each of four defective firebox flue rings of a high pressure Lancashire boiler which may be of interest to many readers of THE BOILERMAKER.

The flues were securely jacked up with timbers at about the center of the boiler; all the rivets were taken out of the front

New Method of Arranging Firebox Flue Rings for Ready Removal

boiler to enable the cutting away of the defective flue rings.

Various methods and practices for drawing out flues are adopted. In some instances, a runway is made in the boiler bottom or rollers are installed, or the flues are placed on a special carriage and with the aid of a crab and rope blocks the flues are drawn sufficiently out of the boiler to enable the cutting away of the defective rings, also the assembling and riveting of the new rings to the existing flues.

The following is a method which proved very satisfactory

end plate and the plate lifted clear of the boiler. The true lengths of the required new flue rings were next obtained.

# OXY-ACETYLENE CUTTING TORCH USED

The oxy-acetylene cutting torch was brought into operation, this machine cutting the fourth ring of each flue, around the plate near the flange. With the aid of a pair of pulley blocks connected to the top center gusset stay the four defective furnace rings of each flue were lifted out of the boiler. When the new four firebox flue rings arrived from the makers riveted and calked on three rings ready for assembling, one was lifted into the boiler with the aid of pulley blocks and bolted closely to the existing flue, which was then riveted.

The second four rings were treated in a similar manner to the first. When the riveting was completed the front end was bolted in position, the rivet holes electrically drilled around the flue ends. Following the riveting and calking the flues were joined to the front end plate. The joint of the new firebox portion with the existing flue rings was calked only in the internal flues.

When completed the boiler was tested to 240 pounds per square inch hydraulic pressure with no sign of leakage at the flue ring joints. The boiler has been in constant service for nine months working at a pressure of 160 pounds per square inch and giving every satisfaction.

#### Advantages Derived by the Above Method

When the defective flue rings are burned off by the oxyacetylene cutter the full diameter of the shell is available for the cutting off and the punching out of the rivets of the existing flue rings, thus requiring no turning and lifting of

# Proposed Standards for Steel Flanges for High Pressure

A COMPREHENSIVE program of standardization of steel flanges and flanged fittings was launched at an open meeting of sub-committee No. 3 held in the rooms of the American Society of Mechanical Engineers, Friday, October 26. This sub-committee is a sub-division of the sectional committee on the Standardization of Pipe Flanges and Fittings which was organized under the procedure of the American Engineering Standards Committee. The three sponsors for this project are: committee of Manufacturers on Standardization of Fittings and Valves, the Heating and Piping Contractors National Association and The American Society of Mechanical Engineers.

The informal conference on this subject which the sponsors held on May 23 indicated such widespread interest in this subject that it was decided to organize a new sub-committee to develop standards for flanges to withstand high superheat temperatures and pressures from 250 to 3,200 pounds per square inch. Professor Collins P. Bliss of the Mechanical Engineering Department of New York University who is chairman of the sectional committee has decided to act also as chairman of this sub-committee. The other members of the Sub-Committee No. 3 are J. C. Bannister, C. W. E. Clarke, Sabin Crocker, R. D. Hall, H. E. Haller, J. A. Hance, C. H. Haupt, H. C. Heaton, J. S. Hess, F. Hodgkinson, D. S. Jacobus, O. F. Junggren, M. B. MacNeille, V. T. Malcolm, W. S. Morrison, W. A. Pope, G. W. Saathoff, J. R. Tanner and H. L. R. Whitney. H. L. R. Whitney of the M. W. Kellogg Company was elected secretary. This list includes official representatives of the American Society for Testing Materials, Hydraulic Society, Power Piping Society, National Electric Light Association, the A.S.M.E. Boiler Code Committee, and the sponsor bodies. A few of the members of this sub-committee were appointed "at large" because of their special interest in and knowledge of this subject.

The open meeting held on October 26 which was also this sub-committee's organization meeting was attended by 50 engineers, manufacturers of this product and users as well. The session lasted all day and the following important actions were taken:

Range of Pressures for Steel Flanges. The maximum steam pressures for which these standard flanges and flange fittings the flues or scaffolding, etc., as in the case when the flues are drawn out of the boiler. No blockage in the firehole when cutting away the defective plates and assembling and riveting the new rings to the existing flue rings is necessary. No crab and wood patching are required.

The chief advantages are at the back end of the boiler, a large percentage of high pressure Lancashire boilers having superheaters attached, entail added cost in taking the superheaters out and replacing them, the necessary brick work that must be removed to enable the taking out of about 126 7%-inch rivets and replacing them and calking around the flue ends all add to the cost of other methods.

The only difficulty in the new method is the riveting of seven rivets down the shell side of the boiler of each connection of the flue rings. The difficulty was easily overcome by one man being on top of the flues and working downwards and one man working upwards from the underside of the flue. When riveting the flue rings, cotter bolts were installed down each side of the shell for bolting up the boiler while assembling the flue plates.

The time taken for the renewal of flue rings by the new method was considerably less than when using the old method.

shall be developed are 250, 400, 600, 900, 1,350, 2,000, 3,200 pounds per square inch. The maximum temperature which they are to be designed to withstand was set at 750 degrees F.

Two Hundred and Fifty and 400 Pounds Steam Standards. These two steel standards are to have the same bolt circle and number of bolts as the present American cast-iron standard for 250 pounds, except that the 2 and  $2\frac{1}{2}$ -inch sizes for the 400 pounds standard will have eight bolts instead of four. The other dimensions of these flanges are, however, to be modified to meet the conditions set for each.

Six Hundred Pounds Steam Standard. The sub-committee further decided to use as the basis of the dimensions of this standard the bolt circle and the number of bolts of the present 800 pounds Hydraulic Standard developed by the A.S.M.E.

Nine Hundred Pounds Steam Standard. The basis for this new steam standard flange is to be the bolt circle and the number of bolts of the present 1,200 pounds Hydraulic Standard developed by the A.S.M.E. committee.

Standards for 1,350, 2,000 and 3,200 Pounds Steam Pressures. Flanges to withstand these pressures and the corresponding superheats are to be developed after the completion of the first four of the series. It will be noted that the seven maximum pressures selected form a geometrical series between the terms 250 and 3,200.

#### SUB-COMMITTEES ELECTED

Realizing the difficulty and inefficiency of 20 men trying to complete the details of these flange standards, Sub-Committee No. 3 elected two sub-committees. One of these headed by A. M. Houser as chairman and Mr. H. L. R. Whitney as secretary, is to select from among the American Society for Testing Materials specifications the one best suited for this purpose and to set the limiting stresses and such tests as are considered to be necessary.

The second subdivision of "No. 3" is to be known as the "Working Committee." It has C. W. E. Clarke as its chairman and Mr. Whitney as secretary. When the working committee receives the report of the sub-committee on the physical and chemical properties it will begin its work on the dimensional standardization. It will then carry on its work intensively since it is required to present its report to the members of the full Sub-Committee No. 3 in writing at least a week prior to the second meeting which was held at the time of the A.S.M.E. Annual Meeting.

# Inspecting Boilers in Holland—

The Dutch Inspector Finds His Chief Employment at Pumping Stations and in the Seaport Towns

# By George Cecil

THE activities of the Dutch boiler inspector are al-

most limitless, for, when the day's work is over, he continues to take life seriously. Ever keen on acquiring knowledge, Frans turns his attention to mechanical engineering and to kindred subjects, "burning the midnight oil" till a late hour in the pursuit of knowledge. He also superintends the education of his children, since the

girls are expected to know something more than the "three R's," while the boys are destined to become, in their turn, boiler inspectors—or, perhaps, full-fledged engineers. So when the children have prepared their task for the next day's class, *Mynheer* puts them through their paces. And woe betide the little Hans, or Gretchen, who fails to afford satisfaction—no snuggling between the sheets till the lesson is learned.—Education bulks large in Holland and the boiler inspector has no intention of wasting school fees on idle scholars. He means to have his money's worth—to the last *florin*.

Sometimes the indefatigable Frans, being dissatisfied with his monthly pay and traveling allowances as a government boiler inspector and with the retiring pension which awaits him after a certain number of years' service, flies at high game. The position and salary of a mill engineer appeal to him, and, to that end, he studies engines and machinery, besides familiarizing himself with the working of each mill which he visits when on his frequent tours of inspection. Every now and then an ambitious man has this desire gratified:-capability and interest combined land him in the hoped-for billet. If, however, the boiler inspector is doomed to remain in his original calling, he does not repine. Frans argues (wise man) that had fortune smiled upon him the job would not have been permanent and that he might, a few years later, have found himself without employmentand, worse still, minus a pension. So, with a degree of philosophy which is not even equaled in the East, the boiler inspector resigns himself to the inevitable, and works none the worse for being disappointed. Decidedly the right spirit.

Other men, though not wanting in ambition, have no intention of deserting "the substance for the shadow." Buoyed up by the pension looming in the future, they are content to rise, in grade succession, to the post of head inspector, a position which carries with it a substantial salary and a fair amount of leisure. "There is," says the Dutch proverb, "a pot of gold at the end of the longest road."

#### THE "TREKSCHUYT AND THE HOOGAAR"

At one time all the pumping stations, being steamoperated, had Frans' attention; now, like many another installation, a percentage are driven by electric power. As, however, at least half of the 565 stations (employed to regulate the water level and to prevent flooding in the reclaimed country) are worked by steam, the boiler inspector cannot say that the bread has been taken from his mouth. The largest of the electric pumping stations, by the way, is at Zoutcamp, near old-world Groningen and has five pumps. The installation, with the exception of those in America, is the largest of its kind in the world.

The twelve important sugar refineries, as well as a number of lesser ones, paper mills, shipbuilding yards, seagoing and river-going steamers, railways and textile mills, also keep Frans busy. Incidentally, traveling to his destination may be a lengthy business, for, the Netherlands being a country of waterways, the journey often is made by canal in a *trekschuyt* (horse-towed barge). Or a *hoogaar* (sailing barge) takes the place of the *trekschuyt* when the destination entails crossing an inland sea to some distant island estuary. But time is not of great importance in Holland; only upon the distance being completed is punctuality expected. Having arrived, the boiler inspector presents himself with clockwork punctuality at the mill or works. More is not expected of him.

#### German Inspectors Invade Holland

Of late a number of German boiler inspectors have found their way into the lowlands—and rather to the indignation of their Dutch *confrères*. The last-named argue that Holland is intended for the Hollanders, and that Germans should earn their living in Germany. Steps, in fact, have been taken to memorialize the Government, especially by the younger members of the corps of boiler inspectors, who declare that to admit the alien is utterly wrong and unfair. The older men, like Brer Rabbit, "lie low and say nothing"; they are too near a well-earned pension to interest themselves in the matter. Besides, Germany and Holland are such good (political) friends that there may be something behind the invasion.

On the eastern frontier, the inhabitants of which are almost as much German as Dutch, little objection is raised to the intruders. When, however, they make their appearance at western Rotterdam and Amsterdam, where steamer boilers, not to mention those of the dock elevators and floating cranes, require attention, the Hollanders are up in arms. Nor does the invaders' lusty singing of "Deutschland über Alles!" help matters!

#### A BORN ECONOMIST

The Netherlands boiler inspector has several excellent characteristics. Ever anxious, for example, to acquire a knowledge of geography, he takes his annual holiday abroad. The well laid-out boulevards of Paris, together with its attractive Bois, have Frans' attention, while he also makes the acquaintance of Vienna and Budapest. A trip is made to Brussels and to Antwerp, and—funds permitting—even to far-distant Naples. He samples London, for which his respect is great; the German itinerary includes Berlin and other important towns; and the Alps are climbed. Upon returning home, the boiler inspector comes to the conclusion that Holland is hard to beat, for he is a true patriot.

These excursions are, of course, expensive. But Frans

is a born economist; he has elevated the art of living on very little money and saving *florins* in every possible direction to a science. And when on his travels the boiler inspector with a thirst for information does not spend a cent more than is necessary, while he subsists-if driven to it-chiefly on soup, bread and cheese. Sight-seeing is considered more important than the call of the stomach. Besides, the traveler is used to a diet in which inexpensive (and nutritious) cheese plays an important part: 'tis the staple food of the Netherlands and he thrives on it. When, however, Frans again finds himself in his native land something more interesting than cheese awaits him. The neighbors, anxious to learn what he thinks of a foreign country, ply him with many a filling dinner, schnapps and advocāat (a cordial in which gin, rum, yolk of egg and sugar are cunningly mixed) being thrown in. The wanderer makes up for his enforced abstinence.

"Does the boiler inspector," you may ask, "take his wife with him?" Most certainly not, for he considers that the suitable place for the *Vrow* is the home circle. Though a fond husband and father, Frans is a practical economist.

### BLACK SHEEP

If the Dutchman of pure blood is a model of all the virtues, the half-breed on the Belgian frontier is the reverse. The admixture of blood, as invariably is the case, has resulted in bad qualities, and the Belgian-Dutch steam machinery users occasionally get themselves into trouble with the authorities. The boiler inspector condemns a boiler as fit for the scrap-heap, to find, on his return visit, that it still is in use-though liable to burst at a moment's notice. When Frans peremptorily orders a thorough overhauling and the substitution of new seamless steel tubes for the old ones, the proprietor of the plant makes promises which he has no intention of keeping! Riveting is jibed at, because it costs money; nothing short of fine and imprisonment will induce the half-caste to replace a damaged gage cock or a worn firebox. Little wonder that the law-abiding Hollanders have a healthy contempt for these people. Elsewhere in Holland such occurrences are well nigh impossible.

The Belgians, for some curious reason, greatly resent the attitude of the Dutch to the boiler users of mixed race, passionately asserting that their misdeeds are exaggerated. The Hollanders retaliate by stating that every half-caste ought to be cleared out of Holland. A drastic measure.

### ACTIVITY IN RETIREMENT

The retired boiler inspector sometimes finds employment in a boiler making concern as shop foreman or in some other capacity. If, however, Frans pines for an existence in which activity is blended with peacefulness, he takes to flower, fruit and vegetable gardening. The national tulip has the veteran's attention, his choice blooms carrying off a prize at the local horticultural show, while the produce of the kitchen garden keeps the table well supplied. The Dutchman is a gardener at heart; consequently, the ex-boiler inspector experiences no difficulty in making a success of horticulture. He may become the envy of the professional grower.

These healthy pursuits are carried out in some picturesque little townlet, where the pensioner inhabits a gabled house of modest dimensions. Or a roomy cottage, the walls of which are distempered yellow, purple, rose, or cream, according to the district, accommodating him. A streamlet, which is crossed by a tiny bridge, separates the property from the road, and the cottage is surrounded by its garden, the chief ornament of which is a lily-laden pond. Here Frans contentedly passes the evening of his days growing prize vegetable-marrows, giant pumpkins, luscious pears and apples of surpassing flavor, and cultivating wonderfully variegated tulips. He asks for nothing better.

In his boiler-inspecting days Frans has eschewed the Dutch costume, which consists of astonishingly shapeless pantaloons, a double-breasted jacket terminating at the waist and buttoning up to the neck, a high peakless cap, and—when pottering about in the mud—glogs. In his retirement he sometimes reverts to this unpretentious garb, the wearing qualities of which are marvellous. Well does it become him.

# Vocational Training Now Open to Adult Workers in Various Industries

A DULT wage earners who wish to receive technical training which will help them in their occupations may now secure such training from the public school, announces the Federal Board for Vocational Education.

Under the Federal and State Vocational Education Acts, funds are available to assist the public schools in each community to set up adult evening classes for wage earners. To receive such instruction, it is necessary that a group of workers, employed in a common industry, take the initiative by organizing themselves into a class. Next, they should present themselves to the local school authorities and request an instructor. The local school board is empowered to provide an instructor and a class room to the applicants. Thereupon, the class begins its sessions on a regular nightly schedule.

In some cases, no instructor, qualified to teach the desired subject, is available. In such cases, the local school authorities may call upon the state supervisor of trade and industrial education. The state supervisor details an instructor to the community. If no technically qualified instructor is available in the state, the supervisor takes steps to train an instructor especially for the needs of the class. In some cases one of the members of the class is given this training to instruct the others. In no case is a group of workers denied assistance until all possible methods of aid have been exhausted.

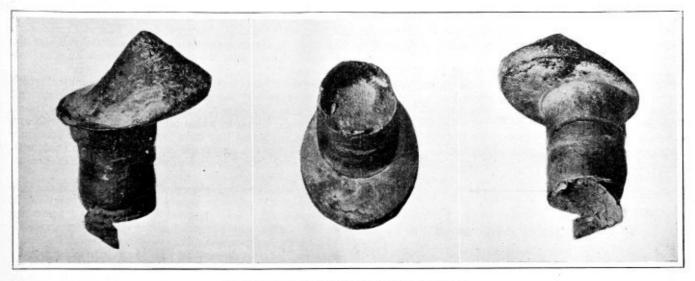

The only restriction that the public schools lay upon such adult extension work is that all members of the class be workers, actually employed in the trades for which they desire training. Thus the mistake of training workers for trades in which they can not get employment is avoided.

Successful results have been obtained through such classes in many communities, the board declares. A notable example has been the work among the coal miners in southern Illinois. Last year over 1,000 miners were enrolled in evening extension classes, studying to qualify for executive positions. The state supervisor reports that, of the many miners who took examinations for higher positions after completing the night school course last year, all passed, giving a 100 percent record to the schools.

Workers in many other communities would duplicate the record of the Illinois miners were they aware that the opportunity of public school instruction is open to them, it is believed. Hitherto, it has been the impression of the general public that public school vocational education was restricted to boys and girls. However, adult education has a high place on the program of the Federal and State Boards of Vocational Education. It is only necessary that the workers themselves take the initiative in asking for it, the Federal Board declares.

INSPECTION BUREAU FINDS DEFECTIVE 55 PERCENT OF LOCOMOTIVES EXAMINED.—The Interstate Commerce Commission's monthly report to the President on condition of railroad equipment shows that during October 6,507 locomotives were inspected by the Bureau of Locomotive Inspection and 55 percent were found defective, while 525 were ordered out of service.

# Some Evidence of the Need for Inspection

Three Views of a Seriously Defective Rivet

'HE illustrations presented herewith show a rivet thatwas recently removed from a steam boiler that had been in active service for no less than eighteen years. It was one of a row of 28 rivets that were similarly defective and it illustrates the kind of work that is too often done in boiler shops where there is no proper supervision. A job of this kind should never be allowed to leave the shop, and any riveter who is willing to turn out such work should either be disciplined in some effective way, or be summarily discharged. The hazards that are unavoidably associated with steam boilers are serious enough and it is unpardonable to increase them, wantonly, by riveting up the joints in so careless a way. It is true that the boiler had held together for a considerable time, but its factor of safety was certainly a good deal smaller than the designer intended, and there is no way of knowing how much longer it could have withstood its load, if it had not come under inspection, which promptly detected the poor workmanship and led to immediate remedial measures, to make the boiler safe.

### DEFECTS IN FORMING RIVET

This specimen illustrates most of the things that can be wrong with a rivet. The most conspicuous feature about it is, that the head is very eccentric, being offset to such an extent that the vertex (or tip) of it comes in direct line with the cylindrical surface of the shank, instead of opposite the center, as it should; and on the other side the edge of the cone falls *inside* of the line of the shank. These malformations were evidently due to lack of even ordinary care in setting the die that shaped the head. The workman certainly knew that the job was a poor one in this respect. He manifestly belonged to the class of men who do not care whether the work they turn out is good or bad, so long as they "get by" with it.

The fin that projects from the head would make it impossible to calk the rivet at this point, in case of leakage.

The rivet head is too small, showing that the original rivet was too short.

The hole for the rivet was punched, and was neither reamed, drilled out, nor even countersunk to remove the burrs; and so far as can be judged from the specimen itself,

*Reprinted from The Travelers Standard.

the line of travel of the punch made a somewhat oblique angle with the plate, instead of being square with it.

The holes in the two plates were not "fair" with each other.

The rivet was too cold when it was driven, and this fact, combined with the poor driving, prevented it from filling the hole properly. An examination of the rivet itself shows that it touched the sides of the hole only at certain spots, and in some places it evidently stood away from the sheet by quite a distance.

The diameter of the rivet hole at its smallest point was probably intended to be about three-quarters of an inch, although the irregularity of the shank makes this somewhat uncertain, and it may be that the intention was to have the hole seven-eighths of an inch in diameter.

Examination of the rivet suggests that the material itself was none too good, for the tail looks to be hard and brittle —possibly from being burned.

Taking all things into consideration, this job is about as poor a one as we have seen in many a day, yet it is by no means a unique or isolated case. Bad workmanship, with its attendant dangers (which may imperil life and property for many years), is altogether too common, and we are far from sure that conditions are improving in this respect. In fact, we are decidedly of the opinion that there has never before been a time when inspection by competent, disinterested men was more needed than it is today. Boilers should be inspected in the shop during construction and the inspection should include both material and workmanship; and further inspections should be made at regular intervals, after the boilers have been put in operation.

# Uniform Cost Accounting

THE Fabricated Production Department of the Chamber of Commerce of the United States has just issued a report containing a summary of the general conference on uniform cost accounting methods recently held at Chicago. The conference, probably the first of its kind ever held, had for its purpose the interchange of accounting experiences in the development and advancement of uniform methods. The report reproduces the leading addresses presented by three trade organization executives representing widely varied industries, namely, malleable castings, tents and awnings, and milk. These industries, according to E. W. Mc-Cullough, manager of the Department, have accomplished great success in their cooperative cost work, and the addresses clearly explain the benefits secured by these three industries as the result of intensive work in uniform cost accounting methods.

The important features of the discussion which took place at the conference also are covered in the report. This informal part of the conference was devoted to a general discussion of four typical and highly important phases of uniform cost accounting.

Initial copies of the report may be had without charge upon request to the Fabricated Production Department, Chamber of Commerce of the United States, Mills Building, Washington.

# Committee on Bolt, Nut and Rivet Standards Approved

THE American Engineering Standards Committee has just approved the personnel of the committee which is developing standards for bolt, nut and rivet proportions under the sponsorship of the Society of Automotive Engineers and the American Society of Mechanical Engineers.

This working committee, which numbers a total of 43 members, 17 of whom represent producers, 24 consumers and 2 general interests, is divided into eight subcommittees, dealing with the following specific subjects:

Large and small rivets. Wrench head bolts and nuts. Slotted head products. Track bolts and nuts. Carriage bolts. Special bolts and nuts for agricultural machinery. Body dimensions and material. Nomenclature.

It is interesting to note that this project originated in a proposal to standardize the widths across flats on nuts and bolt heads, in order to reduce the number of wrenches required to handle the numerous bolts and nuts on machinery and tools. It has often happened that two bolts of the same size would have different nuts or heads, so as to require different wrenches according to the inclinations of individual manufacturers, at very obvious inconvenience and expense to the user.

The chairman of the sectional committee is Professor A. E. Norton of the Mechanical Engineering Department of Harvard University, and the secretary, W. J. Outcalt, of the Standards Department of the General Motors Corpora-tion, Detroit. There are 20 trade and technical societies and groups included in the organization of the committee, namely, the American Electric Railway Association, American So-ciety of Agricultural Engineers, American Hardware Manufacturers Association, American Supply and Machinery Manufacturers Association, American Railway Association (Engineering Division), Associated Manufacturers of Electrical Supplies, Bridge Builders and Structural Society, Electric Power Club, Master Boiler Makers Association, National Machine Tool Builders' Association, U. S. Navy Department, National Association of Stove Manufacturers, Society of Automotive Engineers, Gas Engine and Farm Power Association, Society of Naval Architects and Marine Engineers, American Boiler Manufacturers Association, Railway Car Manufacturers Association, U. S. War Department, American Society of Mechanical Engineers, American Society for Testing Materials; also some manufacturers of bolts and nuts, rivets, wrenches, and machine screws. There are in addition seven independent experts on the committee.

The scope of the work now includes standardization of dimensions, material and nomenclature of all rivets, bolts, nuts, and screws except wood screws, excluding, however, standardization of thread forms, this latter field being covered by the Sectional Committee on Standardization and Unification of Screw Threads, under the same joint sponsorship, in cooperation with the National Screw Thread Commission. This activity is an excellent illustration of the value of the established machinery for carrying on cooperative standardization work.

The American Engineering Standards Committee, which is a federation of the principal national organizations and government departments engaged in standardization work, provides the forum in which all parties concerned with any standard may participate in its formulation under a procedure which assures the democratic representation of all interests. Over 1,000 individuals are now working on such standardization committees.

The part of the work nearest completion is that of the subcommittee on Carriage Bolts, which has issued a report which, after circulation, was approved by the sectional committee by letter ballot, and is now before the sponsors for approval. The report of the subcommittee on Wrench Head Bolts and Nuts has been formulated, and is being circulated generally by the subcommittee for the criticism of American industry.

The personnel of working committees on American Engineering Standards Committee standardization projects is examined by special committees of the American Engineering Standards Committee appointed for the purpose. Their review is to assure a proper balance between producers and consumers and the adequate representation of all essential interests. The committee to review the personnel for this project was headed by Charles A. Mead, as chairman, who is chief engineer, Division of Bridges and Grade Crossings, of the New Jersey Board of Public Utility Commissioners and who represents the American Society of Civil Engineers on the American Engineering Standards Committee.

# Gas Manufacturers to Cooperate With Welding Schools

THE Gas Products Association, headquarters at 140 S. Dearborn street, Chicago, Illinois, recently appointed an educational committee to cooperate with trade and technical schools all over the country in supplying a practical and standard course in welding procedure. The users of oxy-acetylene welding equipment have never been thoroughly satisfied with the work done by welding school graduates, and at the same time the application of the welding processes has been extended to so many new fields that the demand for skilled operators is constantly increasing. It is thought that by making a thorough investigation of the needs of the industry and then making recommendations to welding school instructors, the instruction programs can be revised and standardized so as to more fully meet the requirements of the employers. The plan has been already submitted to some schools and has met with their enthusiastic response, so it is felt that the instructors are honestly desirous of giving the students such training as will guarantee them the very best earning power.

The committee will endeavor to build up a list of accredited schools which are known to give a standard instruction, and whose students can be depended upon to qualify as satisfactory welding operators. It is proposed to make this educational movement effective all over the country, and since the members of the Association have gas and apparatus manufacturing plants in practically all of the important industrial centers of the United States, it is quite likely that this plan can be carried through without difficulty.

# The Boiler Maker

Published Monthly by

SIMMONS-BOARDMAN PUBLISHING COMPANY

EDWARD A. SIMMONS, President HENRY LEE, Vice-President and Treasurer GEORGE SLATE, Business Manager 30 Church Street, New York, N. Y.

Chicago: 608 South Dearborn Street Washington: 425 G Street, N. W. Boston: 294 Washington Street London: 34 Victoria Street, Westminster, S. W. 1

Certain proponents of the arc welding fraternity have apparently acquired the gift of prophecy to a remarkable degree, if certain of the statements appearing in the report on page 307 of the November issue of THE BOILER MAKER, foretelling the relative futures of the arc welding and the oxy-acetylene welding processes are to be taken seriously. Unless these men have been able to look into the future and some distance at that—and have had a vision of developments in arc welding equipment which so far they *alone* have been able to foresee, it is difficult to understand how they can consider themselves qualified to relegate the gas process to the discard, as they so arbitrarily did.

What advances in the art of electric arc welding they

may have had in mind to replace the gas process were not brought out in the report and, as yet, equipment does not exist that by any stretch of the imagination can supplant the torch in many applications where it alone is usable where portability in the field is essential, where electric current is not available, where economy and rapidity in cutting operations must be realized.

Developments in arc welding will be made and new applications are bound to be discovered—yet the gas people are still alive and their progress will inevitably keep pace with the requirements of the field. The fact that they are very much alive to their opportunities is evidenced by the discovery of a new use for the cutting torch by one of the great railroad systems of the country which will save the road thousands of dollars annually.

Every welder who is unbiased in his opinion and interested solely in the development of the welding art realizes that each process has its legitimate field and can best be used as a complement to the other.

Since the American Boiler Manufacturers' Association and the Stoker Manufacturers' Association have been working in conjunction with each other, many of the difficulties of boiler construction and erection of stoker fired boilers have been eliminated and others are in process of settlement. The activities of the members of the Stoker Association which in a way are closely allied to those of the boiler industry are of considerable interest, and the progress of the former organization may to advantage find reflection in the work of the boiler manufacturers.

The keynote of the recent convention of the Stoker Manufacturers' Association was one of progress—not the least important contribution to which was the report proposing the adoption of a uniform cost accounting system for the industry. This report was prepared by a prominent cost accounting firm well known to the boiler manufacturers after a detailed study of conditions in the field of stoker production. The fact that it was adopted in its entirety is sufficient evidence of its value in the minds of the manufacturers of this type of equipment.

The two fields of stoker manufacture and boiler production are quite comparable in their requirements and careful consideration at the forthcoming winter meeting of the American Boiler Manufacturers' Association to be held at the Hollenden Hotel, Cleveland, February 12, might well be given to the study of a similar uniform cost accounting system for the boiler manufacturing industry. Details of this meeting will appear in the January issue.

The annual index of THE BOILER MAKER for the year 1923 will be published separately from the magazine at the end of the year. As the complete index will be useful only to those of our subscribers who have kept a complete file of the magazine for the year, only a sufficient number of copies will be printed to meet the requirements of those who notify us at once of their desire for a copy.

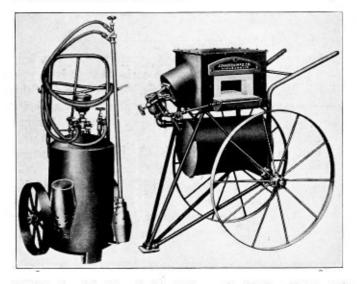

A copy of the annual index will be mailed without cost to each subscriber whose request for it is received at our New York office on or before January 1.

# Engineering Specialties for Boiler Making

New Tools, Machinery, Appliances and Supplies for the Boiler Shop and Improved Fittings for Boilers

# **Oil-Burning Rivet Forges and Torches**

A LINE of modern rivet forges with non-clogging vacuum oil burners, oil-burning torches, and pressure blowers has been developed and recently placed on the market by the Johnston Manufacturing Company, Minneapolis, Minn. The rivet forge, shown in one of the illustrations, is made in three styles, No. 1 for car repair yards, No. 2 for structural steel shops and No. 3 for boiler shops.

Oil-Burning Torch and Rivet Forge for Boiler Shops and Car Repairs

The only difference in these forges is in the capacity of the burners, the No. 3 forge having about one-fourth the capacity of the burner on the No. 1. All the burners are adjustable through the usual range of about one to three, but best results are obtained by having the burner on each forge adapted to its specific use.

Aside from strength and easy portability by means of the large-diameter, ball-bearing wheels with wide tires, the principal feature of this rivet forge is the non-clogging vacuum oil burner. In order to avoid the formation of scale on rivets a uniform flame is necessary, obtainable only by maintaining the oil feed in proper proportion to the air. To accomplish this result the Johnston oil burner was developed with an air inlet valve by which the oil feed is regulated indirectly. This air valve does not clog since only air passes through it and as the air passages in the burner are larger and direct, the oil flow tends to remain uniform, and the character of the gases in the heating_chamber consequently remains as first adjusted.

To overcome difficulty from variable air pressure in shops, this burner was so designed that the vacuum by which the oil is drawn up varies directly as the air pressure. The relation between the air and oil supply are, therefore, automatically maintained as first adjusted regardless of changes in air pressure. As a result of the non-clogging feature and provision to offset variable air pressure the character of the flame remains constant; scaling and smoking are reduced to a minimum and the forge operates at high combustion efficiency. The burner has a high vacuum and large oil connections, enabling heavy oil to be used.

The frame of this forge is in the form of a triangle, providing maximum strength and rigidity in proportion to weight. This is a valuable feature, in view of the use and abuse to which rivet forges are put in the course of everyday service.

Forge linings often fail by burning through at the top where the flame strikes and by cracking and spalling around the charging opening. In the Johnston forge the linings are not less than  $4\frac{1}{2}$  inches thick where the flames strike and with a charging opening 6 inches wide there is little tendency for this opening to become enlarged by cracking. Additional features are the pivoted tongue which acts as a guard for the burner, the filling funnel and strainer, the air curtain pipe to deflect the hot gases upward and the welded oil tank which has a capacity to hold 20 gallons of fuel oil.

#### OIL BURNING TORCHES

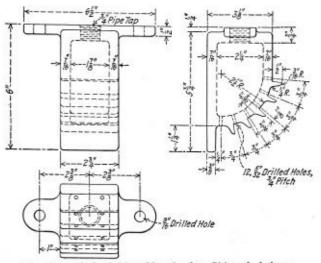

The oil-burning torch illustrated is made in two styles, No. 20 for shop work and No. 21 for firing locomotives for steam test or for starting coal fires in locomotives. The difference between the two styles is in the capacity of the atomizer, the first using 15 gallons of oil an hour and the second 35. This torch, known as the "one man portable," is featured by high capacity and light weight combined with rugged design. This is accomplished by using light, practically unbreakable cast steel nozzles and one large pipe from the torch head to the hose connection. This single pipe is strong and easy to hold. Instantaneous ignition and steady operation are accomplished by a new type atomizer which breaks the oil up into a fine fog close to the torch head and permits the use of a short, and therefore light, single chamber nozzle. Pressure in the oil tank is blown down through the air connection, and this operation does not spray oil over the operator. The filling funnel has a strainer in which the dirt collects and is effectually prevented from entering the tank. Plug cocks are used on air and filling connections for quick and easy operation. The oil hose is protected by an automatic valve which closes in case of failure of the oil hose.

This torch has a wide range of capacity with either nozzle. The large nozzle operates from a small flame 12 inches long up to the big flame required for firing a locomotive boiler for the steam test. Another feature is the tubular handle for the tank, providing a light, convenient grip. The length of hose furnished is  $12\frac{1}{2}$  feet. As in the case of the rivet forge the oil tank is welded. It has a capacity of 20 gallons. An extra nozzle for the torch is carried on a bracket as shown in the illustration, being always available. The nozzles are designed to run at moderate temperatures, giving long life.

FRANK C. PICKARD, master mechanic of the Delaware, Lackawanna & Western at Buffalo, has resigned, effective November 30, to take a position with the Talmage Manufacturing Company at Cleveland.

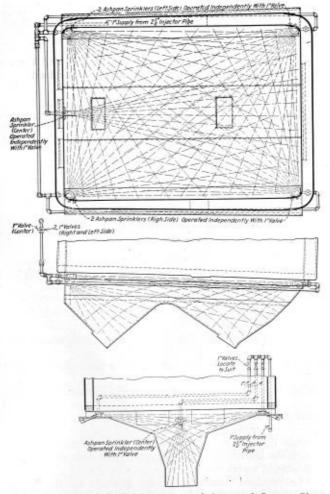

# Ash Pan Sprinkler and Cleaner

THE Pratte Vacuum Air Sander Company, Denver, Col., has on the market an ash pan sprinkler and cleaner of unique design. Water is piped through a 1-inch pipe from the injector pipe to a number of sprinklers

Drawing of Sprinkler Nozzle for Side of Ashpan

located at strategic points at the center and sides of the ash pan. The water is turned into the supply pipes by a valve in the cab. As shown in the illustration, the sprinkler is designed to spray the water over a large area. The number

Arrangement of Sprinkler on an Ashpan of Large Size

of sprinklers required depends upon the size of the ash pan. On a pan of 11 feet or more it is recommended that a sprinkler be placed at each corner.

With boiler pressure behind the stream, any fire shaken through the grates can readily be put out and the ash pan given a thorough cleaning. It is claimed that where this device is installed on locomotives, cleaning the ash pans with a hose at terminals is practically eliminated. A better draft through the grates is obtained with a clean ash pan and considerable saving is accomplished as the pan will not warp when this device is used.

# Portable Electrical Recording Instrument

MONG the recent developments by the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., is a new portable recording instrument known as type R. It is made for applications where records as accurate and reliable as those obtained with large switchboard instruments are necessary. Such applications include analysis of motor operation, typical consumption curves of large industrial consumers, and records of power distribution.

The type R instrument is an adaptation of the switchboard recording instrument, with the element as a whole mounted in a portable carrying case. An electric self-winding clock is used for speeds up to 24 inches per hour. For slower speeds, up to four inches per hour, a hand-wound clock can be used.

Alternating current ammeters, alternating and direct current voltmeters, and single and polyphase wattmeters are made in these portable recording instruments.

# BUSINESS NOTES

James J. Dale has resigned as vice-president and director of the Consolidated Machine Tool Corporation, New York.

The American Car & Foundry Company has ordered the structural steel for a foundry at Madison, Ill., from the Kenwood Bridge Company.

C. A. Dunn, formerly sales manager of The Weldless Tube Company, has been appointed manager of the Delaware Seamless Tube Company, Auburn, Pa.

D. P. Bennett, vice-president of the Pittsburgh Steel Company, Pittsburgh, Pa., has been elected president, and E. H. Bindley, a director, has been elected vice-president. Henry J. Miller was elected a director to succeed the late Willis T. McCook.

R. P. McCormick will have supervision of the sales activities of the Eastern district for the Pawling & Harnischfeger Company, Milwaukee. He will have offices at 30 Church street, New York, and 605 Stephen Girard building, Philadelphia, Pa.

The Mahr Manufacturing Company, of Minneapolis, Minn., manufacturers of rivet forges, torches, furnaces and kindred oil-burning equipment, has moved its New York office from 56 Murray street to larger quarters at 42 Murray street. Ray G. White is the district representative of the company at New York.

The Linde Air Products Company, New York, recently started continuous operations in its new plant at Tulsa, Okla. Oxygen will be extracted from the air by the liquefaction process. The plant is also able to reclaim the nitrogen and separate the rare gases, argon and neon. C. A. Kennedy is operating superintendent. A Prest-O-Lite plant, for the manufacture of welding and cutting gas, is also planned for the same locality.

# Questions and Answers for Boiler Makers

Information for Those Who Design, Construct, Erect, Inspect and Repair Boilers-Practical Boiler Shop Problems

Conducted by C. B. Lindstrom

This department is open to subscribers of THE BOILER MAKER for the purpose of helping those who desire assistance on practical boiler shop problems. All questions should be definitely stated and clearly written in ink, or typewritten, on one side of the paper, and sketches furnished if necessary. Inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

# Proportions for Cast Steel Rings

Q.—Can you help me in working out the following question? Data: Tank like sketch, Fig. 1, for 300 pounds working pressure. Have no trouble with the thickness of the shell and heads, of course, as the regular rules as given in any of the code books apply all right to these thicknesses. Now how do I arrive at the following dimensions of the cast steel rings by application of rules that I can understand and use for any similar case: Assume roughly a diameter of 70% inches for "C" if you think it all right. Required: 1. How thick shall "B" be made, so as to be strong enough; how do you figure it? 2. How do you figure the number of rivets for attaching "B" to end head? 3. How do you figure thickness of both forme "t"

How do you figure thickness of bolt flange "A" so as to be strong

head?
3. How do you figure thickness of bolt flange "A" so as to be strong enough?
4. How do you figure the number and size of the bolts for "A"?
In figuring the number of bolts required, how do you apply the rule for "wrench" pull on bolts, and how do you get so-called "axial" stress in connection with the "wrench pull."
Assume steel castings for rings or flanges, and mild specifications, say 60,000 pounds tensile strength.
As to the number of bolts, do you figure load on same from "test pressure." when you consider the "wrench pull." or do you figure the load from the "wrench pull." and "axial stress" so anyone can understand it. Have use for this information every week or so, and cannot find any satisfactory way of figuring the above out and proving it. Ny second question is this: Take a bolt of the shape shown in sketch: Now how do figure." Ist. How much will this bolt support in this shape; how is it figured? Disregard load on pin, as I am interested in the U-shaped bolt and bearing plate only.
The something like a half of a chain link, but I don't know how to apply a rule to it to figure it out. Several of us have tried our hands at it but cannot get anywhere with it.

A .- The plate thickness required for the shell, Fig. 2, is found from the formula

$$P = \frac{TS \times t \times E}{\substack{R \times f \\ P \times R \times f}}$$
(1)  
$$t = \frac{P \times R \times f}{TS \times E}$$
(2)

and

- in which P = allowable working pressure, pounds per square inch.
  - t =thickness of plate, inches.
  - E = efficiency of riveted joint, in percentage.
  - TS = tensile strength of plate, pounds per square inch.
    - R = inside radius of shell, inches.
    - f = factor of safety.
- *Example:* Given the following values: P = 300, E = 0.90,R = 30, TS = 55,000 and f = 5. Determine the re-
- quired thickness of shell plate. Solution: Use the values given in formula (2)
- $300 \times 30 \times 5$ - = 0.91 inches, say 1 inch for this Then t = $55,000 \times 0.90$

problem.

The unit crushing stress in front of the rivets a or the shearing stress in the metal b-b, Fig. 2, is found from the formula

$$W = S \times A \qquad (1)$$

$$W = \frac{W}{S} \qquad (2)$$

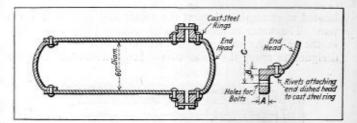

in which W = the unit stress in pounds.

and

S = the allowable stress for shearing, or crushing, pounds per square inch.

A = sectional area required to resist shearing or crushing.

The application of these formulas cannot be made until

#### Fig. 1.-Problem to Determine Design of Cast Steel Rings on Tank. Detail of Joint Between Ring and Head Shown at Right

the load on each inch of the circumferential length of the shell is determined.

First find the total load on the head from the formula,  $W_1 = d^2 \times 0.7854 \times P$ 

 $W_1 =$ total pressure on the head end of the cylinder in pounds.

d = inside diameter of shell, inches.

P == working pressure, pounds per square inch. Example: Substitute the values of the example in the formula given.

Then  $W_1 = 60^2 \times 0.7854 \times 300 = 848,232$  pounds.

The unit stress in 1 inch of the circumference of the shell equals

$$4,500$$
 pounds.

The load tending to shear or crush the ring equals 
$$W = W$$

$$S \times A$$
, and  $A = -$ . Allowing a safe stress of 5,000

pounds for either of these conditions, the sectional area should 4.500

equal 
$$A = \frac{1}{5,000} = 0.9$$
 inch.

Since the load is figured for a circumferential length of 1 inch the thickness of the flange for an area of 0.9 square inch should equal 0.9 inch.

The required number of bolts depends on the diameter of the bolt circle, the safe stress per square inch of bolt section. Assume that 7/8 inch bolts are used. For a good forged bolt 7/8 inch in diameter it will safely carry 4,580 pounds. Owing to the distance required between bolt heads for turning them into place it will be necessary to use two bolt circles, in which case the bolts are staggered. The width of hexagonal nuts across corners equals 1 19/32 inches which would require a pitch of at least 21/4 inches between bolt centers.

The internal diameter of the shell equals 60 inches, the shell plate thickness equals 1 inch, the thickness of the flange of the ring where it is riveted to the shell equals 0.9 inch and the center of the first bolt circle is 21/4 inches from the inside face of the flange.

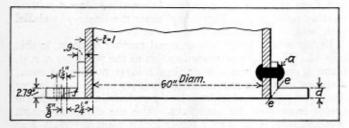

The sum of these respective lengths is as follows:  $60 + (2 \times 1) + (2 \times 0.9) + (2 \times 2\frac{1}{4}) = 68.3$  inches. The circumference of this circle equals  $3.1416 \times 68.3 =$ .214.57 inches.

The required number of bolts equals 848,232 ÷ 4,580 -182.

Using 91 bolts in each circle, the pitch between the centers of the bolts in the inner circle equals  $214.57 \div 91 = 2.35$ inches.

The distance between the bolt circles may be made 11/4 inches, in which case the bolts in the outer circle stagger those in the inner row and are equally spaced.

The next calculation is to determine the thickness of the flange d, which must be sufficient to resist bending and

breaking along the plane e-e. Consider the section from the inside of the flange to the point f midway between the bolt circles as a cantilever beam. The length of the beam equals 2.25 + 0.625 = 2.875 inches.

The bending moment equals;

M = lW

in which M = bending moment, inch pounds.

l =length of cantilever.

$$W = load$$
 in pounds.

Substitute in the formula the values l = 27/8 and W =4,500

 $M = 2.875 \times 4,500 = 12,937.5.$ Then

The section modulus required equals the bending moment divided by the allowable bending stress of the material. Allowing 10,000 pounds as the safe bending stress, the section modulus equals

 $12,937.5 \div 10,000 = 1.29375$ , say 1.3

The section modulus formula for a rectangular section equals

 $Q = \frac{b d^2}{6}$ 

in which Q = section modulus.

b = shortest side of rectangle, inches.

d =longest side of rectangle, inches.  $b d^2$ 

Therefore,

and as b = 1 inch

0

$$V = \sqrt{\frac{Q \times 6}{1}} = \sqrt{\frac{1.3 \times 6}{1}} = 2.79$$
 inches, the equired thickness of the outer leg of the ring at d. Fig. 2.

required thickness of the outer leg of the ring at d, Fig. 2.

#### WRENCH SIZES

The size of wrench for bolting up as determined by Crane and Company is as follows: Tests show that a compression of 12,000 pounds nearly can be obtained by a man using a 16-inch wrench on 34 and 1-inch bolts; a 36-inch wrench on 11/8 to 13/8-inch bolts; a 60-inch wrench on 11/2 to 13/4inch bolts and a 72-inch wrench on 17% to 2-inch bolts. Square nuts give from 20 to 25 percent less compression than hexagon nuts with a given effort on the wrench.

Lubrication of threads and bearing surfaces increases compression 10 to 15 percent over that obtained with bolt surfaces not lubricated. There is danger of excessive stress being set up in bolts 1 inch in diameter and less. The wrench pull therefore should not exceed that for which it will safely carry; which may be guarded against by using wrenches of the proper length. The following overall lengths of box wrenches are recommended:

Size of bolt, inches ..... 3/4 7/8 1 Size of wrench, inches ..... 111/2 131/4 15 11/4

19

Axial stress is the stress in the plane of and parallel with the axis or center line of the member.

The weakest section of the U-bolt is at the bend which is subjected to a bending stress. The bending moment equals  $W \times l$ 

$$M = \frac{1}{20}$$

in which M = bending moment, inch pounds.

W = load on bolt. l =inside diameter of bend.

Divide the bending moment by the allowable working stress which, for bar sections used, equals 6,000. This gives the section modulus.

The section modulus formula for a round section equals  $3.1416 \times d^{3}$ 

$$Q = \frac{1}{32}$$
 or  $0.0982 \times d^3$ .

Transposing the formula to find d when Q is known

 $d^3 = \sqrt{\frac{Q}{.0982}}$ 

in which d = diameter of the round bar in inches.

Assume that the U-bolt is required to support a load of 10,000 pounds and that the inside diameter of the bend equals 21/4 inches.

Then 
$$M = \frac{10,000 \times 2.25}{20} = 1.125$$
 inch-pounds.

$$1,125 \div 6,000 = 0.187$$
, the section modulus.  
The value of  $d = \sqrt[6]{\frac{1.187}{.187}} = 1\frac{1}{4}$  inches, nearly.

value of 
$$d = \sqrt[4]{.0982} = 1\frac{1}{4}$$
 i

# **Boiler Horsepower**

Q.—I am taking the liberty to write to you for the following information: Will you kindly give me the formula for calculating boiler horsepower for both tubular and watertube boilers? I want a general formula that is applica-ble to any boiler of either of the above type regardless of size, providing there is such a formula. If it is not asking too much, could you forward the above to me by mail? Perhaps the answer to my wants would be of some use to a great many other readers of THE BOILER MAKER, and if space would permit I am sure that the publication of the answer to the above would be appreciated by quite a few.—C. H. P.

A .- The commercial horsepower of boilers is dependent on the number of square feet of heating surface and the general design of the boiler. The number of square feet per horsepower has been approximated for different types of boilers. This method is employed by manufacturers in stating closely the boiler horsepower. Some types of boilers are more efficient than others in the evaporation of water.

The definite method of determining the horsepower is by tests. The evaporation of 30 pounds of water per hour from a feedwater temperature of 100 degrees F. into steam at 70 pounds gage pressure, which is equivalent to the evaporation of 34.5 pounds of water from and at 212 degrees F. into steam at the same temperature. The A.S.M.E. give 970.4 British thermal units as required to evaporate 1 pound of water from and at 212 degrees F., hence 970.4  $\times$  34.5 = 33,479 British thermal units per hour transmitted from the fuel to the water. This constitutes the heat value in a boiler horsepower.

The following table gives the approximate number of square feet of heating surface per boiler horsepower for the different types of boilers.

Types of Boiler	Square Feet of Heating Surface Per Boiler Horsepower
Water tube	10 to 12
Tubular	14 to 18
Flue	
Locomotive	
Vertical tubular	15 to 20

# Steaming Capacity of Boilers

Q.-During my negotiations with big boiler manufacturers in this country (England) I was approached by one who is very anxious to obtain certain information which I will briefly explain: They have received inquiries from the states to replace American boilers by their own patent boilers, the American boilers having the following particulars: (1) Boiler 3 feet 6 inches diameter by 7 feet 0 inches high with 116 vertical 2-inch outside diameter fue tubes. (2) Boiler 5 feet 2 inches diameter by 9 feet 1 inch high, having 320 134-inch outside diameter tubes. As they are unable to obtain the exact steaming capacity of these boilers so as to offer a similar English boiler. I was wondering whether you could furnish me with these particulars? The firm in question is to bring out several new designs in the near future and I would like to help them if I possibly could.-F. G. B.

A.—The steaming capacity of a boiler is dependent, not only on the amount of heating surface, but also on the size of furnace, combustion space, grate area and their general arrangement.

A boiler may have a large heating surface, yet be a poor steam producer, on account of poor design.

In order to answer your question, further data is required on the size of the furnace or firebox, length of tubes, etc.

# Wrapper Sheet Camber Layout

Q.—I am inclosing a sketch of a wrapper sheet camber layout in which the points projected by using the method explained in THE BOILER MAKER on page 241 do not seem to work out for some reason. I have followed the rules and formula very closely and have checked the work but somehow the stretchout arc did not intersect the points they were intended to. These points are indicated by small circles in the sketch. The reason the curve was drawn with the tranmels was to check the work. I note that the dimensions are given in inches but suppose if they were in feet I could use this method of camber layout. Will you please explain regarding this problem. It seems to be a very good method to layout a camber providing the taper for the sheet is known.—M. M.

A.—The solution given in the August issue by R. L. Phelps, for the development of a frustum of a cone is correct. In your sketch you made a mistake in applying the method, which you will understand from the development, Fig. 1, and the following explanation: The elevation of a cone 2 inches in height, having a large base, M-N, 3 inches in diameter and a smaller base O-P, 2 inches in diameter. Extend the base line M-N and make m-n equal to  $3.1416 \times 3$ 

= 4.71 inches. The length s-p equals 2

 $3.1416 \times 2$ 

-=3.1416 inches, which equals the stretch-2

out of the small end. From p and at right angles to s-p

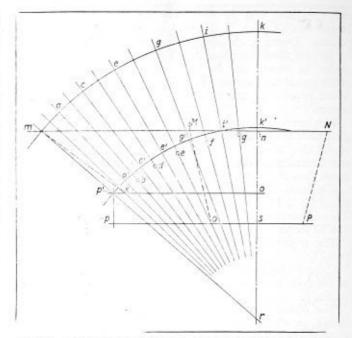

Fig. 1.-Method of Developing a Wrapper Sheet Camber

draw the line p-p'. Use the slant height M-N of the frustrum and from point m draw an arc intersecting line p-p' thus locating point at p'. Through p' draw the line o-p' parallel with m-n.

Divide m-n and o-p' into an equal number of parts, in this case 12. To secure accurate location of the points a, c, e, g, i and k on the large camber line, a large number of equal divisions should be used. Extend m-p' to intersect the center line as at point r; also draw in the radial lines through the points located on the stretchout. Use the diagonal length m-x and with point x as a center locate point a. With a as a center locate point b, then c, d, e, f, etc. Using the slant height of the frustrum as m-p' and from points a, c, e, g, i and k locate the points a', c', e', g', i' and k' which lie on the camber of the small end. By using the radii r-m and r-p' it will be seen that the curves for the large and small ends pass through the points located.

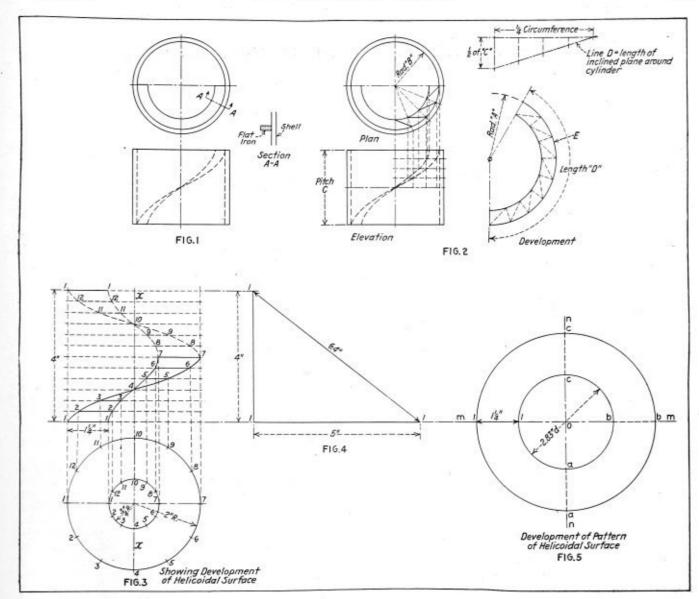

# Calculations and Development of a Helicoidal Surface

**Check Constant and Section 1** The state of the state of

A .- The solution of this problem in accordance with the specification stated can be solved for practical purposes as given in Fig. 3, based on the following explanation:

The helix construction is shown in Fig. 1 and the surface between the points I-I-I of the inner and outer helices is referred to as a helicoidal surface. It will be observed from the construction, Fig. 1, that the surface is developed by a

#### THE BOILER MAKER

Layout of Small Helicoidal Surface

straight line I-I that is perpendicular to the axis x-x of the cylinder as the surface is wound so to speak around the cylinder to make a complete turn in the distance y, called the *pitch*.

The helical curves are developed by dividing the circles in the plan which represent the path of helices in that view and by dividing the corresponding pitch y into the same number of equal parts. The vertical projections from the points t to  $t^2$  inclusive are drawn from the plan to intersect the corresponding horizontal projectors in the elevation, thus locating points on the inner and outer helices.

The length of the inner helix is equal to the hypotenuse of the right angled triangle, Fig. 2, of which the base equals the circumference of the inner circle plan view and the height of the triangle is equal to the pitch y. The dimensions of a given helicoidal surface are given in Fig 1. Thus the pitch y equals 4 inches, outside diameter of helicoid equals 4 inches, and the inside diameter  $1\frac{1}{2}$  inches. The base *I*-*I* of Fig. 2 equals the circumference of the  $1\frac{1}{2}$ -inch circle plan view, Fig. 1 or  $1\frac{1}{2} \times 3.1416 = 5$  inches. The height of the triangle, Fig. 2, equals 4 inches and the hypotenuse equals  $\sqrt{5^2 + 4^2} = 6.4$  inches.

From these data the pattern for the complete turn of the helicoid, Fig. 3, may be calculated very closely and developed

as shown in the illustration. The circumference of the inner circle, Fig. 3, equals the length of the hypotenuse, Fig. 2 or 6.4 inches. The diameter of a circle having this length equals  $\sqrt{\frac{6.4}{.7854}} = 2.83$  inches. Layoff the lines m-m and n-n at right angles to each other. From point o describe a circle with a radius of  $\frac{2.83}{.2} = 1.415$  inches. From point I set off the length I-I equal to  $1\frac{1}{4}$  inches and draw the outer circle from point o as a center. If the helicoid is of large size the pattern can be split into as many sections as desired. For example, it is divided into four parts as indicated along the lines I-I, a-a, b-b and c-c. In

The Interstate Commerce Commission has reopened its investigation into the cost of construction and repair of railway equipment in so far as it pertains to locomotives on the Erie. This is the proceeding in which the commission criticised certain railroads for the amount of the expenditures for repairs to locomotives in outside shops during 1920.

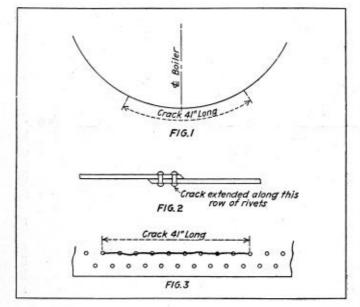

such cases allowances are necessary for laps at the joints.

# Letters from Practical Boiler Makers

# **Unusual Barrel Sheet Failure**

R ECENTLY while inspecting Okmulgee Northern engine No. 2 preparatory to general repairs, a somewhat unusual defect was discovered by boiler inspector J. H. Dozier of the K.O. and G.R.R., at Muskogee, Okla., where the engine is now in the back shop. Noting evidence of leaks in the middle girth seam, the jacket was removed and a crack was discovered zig-zagging from side to side of the rivet

Details of Crack in Barrel Sheet

holes in the back seam of the outer lap for about 20 inches each side of the center line of the boiler. It was necessary to apply a patch 10 inches wide by 64 inches long. It is not known how long this condition had existed nor the cause.

The accompanying sketches will indicate the location and character of what to local boiler makers constitutes an unusual defect.

Muskogee, Okla.

M. H. LEARNARD.

# What is the Inspector's Duty?

ONE could not help but realize on reading the report of the Bureau of Locomotive Inspection, as given in the August issue of THE BOILER MAKER, how very important it is that boiler inspectors should be competent. In view of the boiler failures, as noted in the report, the question is most urgent.

Taking the case of failure of crown sheet, the condition of crown bolts as shown by sketches prove that something was rotten somewhere, either in the inspection or the supervision. Those conditions could not have developed in one day or a dozen. The failure of the back head, as noted in case 2, shows that all the fools are not dead yet, and a foreman that will have a repair of that kind made should be relieved of his job and given his proper tools,—a wheel-barrow, shovel and a broom.

The two arch tube failures as given in case 3-4, what a sad commentary on the efficiency of inspectors or supervisors. Where is the blame to be laid? Does the inspector see these defects and is he afraid to report them for fear of being bawled out by the foreman for wanting to tie the engines up? Such incidents are common in the daily routine of a boiler inspector, but should not be. Too often the boiler inspector is given to understand that it is not for the amount of work that he can find, that he is there, but rather for how little he reports.

#### INSPECTOR'S POSITION IN CASE

In discussing these boiler failures with men in the shop, the inspector's side of the case was thus spoken of: What is he to do if he has a foreman that can only see one thing, and that is, get the engines out, and the foreman is, as it were, the final court of appeal? Then I say, take the boiler inspector from under the jurisdiction of any one less than the superintendent of motive power.

Railroad officials cannot recognize any too soon that a competent and unhampered boiler inspector is one of the best paying propositions they can have. In reporting and having small defects repaired before they grow into bigger ones they save the companies thousands of dollars, and, undoubtedly, proper inspection will in the long run save them, not only from heavy financial loss, but also from a lot of unenviable notoriety. A good inspector can have only one viewpoint, safety first as applied to the boilers that come under his care.

I can think of nothing the editors of THE BOILER MAKER can do that will be of more benefit to everybody concerned than insisting and suggesting a genuine clean-up along the lines of boiler inspection.

JOSEPH SMITH.

# A Scotch Boiler Without Stays

THE cleaning of the outside of the combustion chamber in Scotch marine boilers is made nearly impossible by the great number of screw stays and, as the most efficient heating surface is formed by the combustion chamber plates, the steam production quality of a boiler will be much better if cleaning at regular times is possible, especially when no surface condensing apparatus is installed.

For this reason a boiler design has been worked out and patented in many countries by a Dutch firm. It is shown in the accompanying illustrations which are self-explanatory.

The end plates are arched in order to avoid the troublesome steam space stays.

The advantages claimed for the new design are:

The boiler is easily made at lower cost.

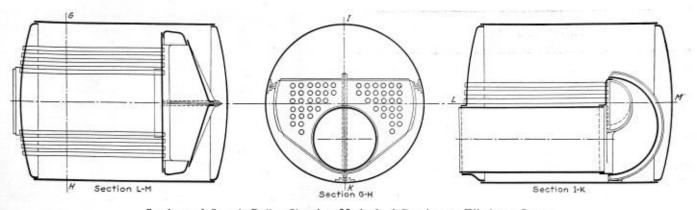

Ample space for the gases for more complete combustion and for entering into the tubes is provided.

Easy cleaning is a special feature.

Better water circulation is realized.

No resistance is offered to the expansion of the furnaces

Lorain, Ohio.

Sections of Scotch Boiler Showing Method of Bracing to Eliminate Stays

and the tubes in this special type of construction. Repairs can be made at small cost.

The design has also been applied to boilers with two furnaces.

Dordrecht, Holland.

BOILER REPAIRER.

# Experts Needed for Safe Boiler Inspections

THE explosion as set forth on page 267 of the September issue of THE BOILER MAKER was very disastrous and for a point of argument I would like to have our readers inform me how can grooving along the shell or barrel of this type of boiler be detected. Of course many will readily come forth with the suggestion that it could be found with a hammer but I disagree there for it cannot always be so found. Neither could it be found by visual inspection for it was not visible to the eye at the time of the hydrostatic test nor could it be seen through the washout plug in the front head, for the defect was apparently 3 or 4 feet from the front head.

As long as we allow lap seam boilers to be operated, we are going to have explosions from the source that caused this one and I earnestly believe that inasmuch as we only allow 100 pounds on lap seams of new construction we should also cut down to 100 pounds all lap seams of old boilers that are in existing installations.

#### DRAWBACKS OF HYDROSTATIC TESTS

This also goes to show that the hydrostatic pressure is not to be depended upon for I have noted several cases where it has failed to disclose serious defects.

Not only did the grooving cause the trouble, but the boiler was being operated at an excess pressure. What did the mechanic know about boilers to assert that 135 pounds be allowed? Using a 5/16-inch plate and staybolts spaced 5 inches by 5 inches under new construction, the boiler would only be allowed 110 pounds working pressure. This boiler, having plates  $\frac{1}{4}$  of an inch thick, would certainly not be allowed 100 pounds.

The efficiency of the longitudinal joint was 69.6 percent, therefore

 $\frac{25 \times 60,000 \times 0.696}{17} = \frac{1,044}{17} \text{ or } 614 \text{ pounds bursting}$ 

pressure.

614

= 4.65 factor of safety.

They were no doubt operating under the factor of safety of 4.65. The writer does give us the age of the boiler but it is by no means of modern design or workmanship and I am at a loss to understand where he obtains 60,000 pounds tensile strength for certainly it could not be found stamped on the sheets after a boiler had gone through the weather and handling that this type of boiler gets.

Where was the inspector, who would allow 150 pounds pressure on a boiler when by using the factor of safety of five he would only allow 122.8 pounds per square inch? This explosion ought to be a lesson to others using lap joint construction that they should when undergoing extensive repairs and hydrostatic or hammer test call in the services of one trained in that line and not any old handy man who thinks he knows all about the boiler simply because he has been around them a year or two. If you hire the services of a doctor you don't call in a quack and if you want a lawyer you don't send for a shyster. Therefore, why call in a shoemaker to work on such a dangerous article as a steam boiler when the skill of an expert is required?

Port Dickinson, N. Y.

# **Government Inspector's Report**

INSPECTOR.

#### (Continued from page 339)

Southampton street, Boston, May 19, 1923, showing condition of firebox sheets and flues "Good—Good," and approved by the officer in charge.

Monthly locomotive inspection and repair report made at Southampton street, Boston, under date of June 7, 1923, signed and sworn to by the inspector, and approved by the officer in charge; monthly locomotive inspection and repair reports made at Southampton street, Boston, under date of July 7 and August 7, 1923, signed and sworn to by the inspector, and approved by the officer in charge, all of which show the condition of flues and firebox sheets "Good— Good."

#### CONCLUSIONS DRAWN FROM FAILURE

It certainly could not be said that a firebox patched to the extent, as the records show in May, 1922, and to the extent that was found at the investigation of this accident, could be termed in good condition, nor is it at all likely that all firebox leaks which were reported during the month of August developed after the report of August 7 was made.

While it is evident that this accident was primarily due to the failure of the crown sheet because of having been overheated due to low water, it is apparent that the violence of the explosion was increased by the failure of the welded seams, contributed to by two adjacent broken crown stays, and our investigation further made it apparent that the sworn reports covering the condition of this firebox prior to the accident do not represent the true condition.

# NEW BOOKS

LOCOMOTIVE CATECHISM. By Robert Grimshaw, 958 pages, 5½ inches by 734 inches, 468 illustrations, bound in cloth. New York: 1923. Norman W. Henly Publishing Company.

This is the thirtieth edition of a book which for a number of years has been considered the standard authority in its class. It is written in a simple and easily understandable manner such as will appeal to firemen, engineers, trainmen, switchmen, shop hands and enginehouse men for whom it has been prepared. The text follows the form of examination questions and answers, of which there are some four thousand. Considerable new matter has been added in this addition and the old matter carefully revised. The chapters, of which there are 89, are short and conveniently headed for ready reference and cover the various details, such as boilers, cylinders, valve gear, running gear, superheaters, air brakes, etc. The book tells not only what to do, but also what not to do and is specially helpful for a person preparing for an examination for promotion.

WELDING CYCLOPEDIA. Edited by L. B. McKenzie and H. S. Card, 438 pages, illustrated, 6 inches by 9 inches. Bound in flexible imitation leather. Chicago: 1923. The Welding Engineer Publishing Co.

This is the third and enlarged edition of a reference book on the theory, practice and application of autogenous welding processes. The first half of the book consists of a dictionary of the terms used in the industry, together with instructions for welding operations of the usual type. Succeeding chapters treat of electric arc welding, electric resistance welding, oxy-acetylene welding and thermit welding in detail. A further section covers the rules and regulations of federal and state authorities and insurance companies. Various charts and tables are included, and at the end of the book is a comprehensive catalogue of welding apparatus and equipment. In this edition information has been added on the training of operators and considerable new material relative to special welding jobs—including tanks, pipes and plate work—has been included.

KENT'S MECHANICAL ENGINEERS' HANDBOOK. Robert P. Kent, editor-in-chief. Tenth edition; 2,247 pages, 4¼ inches by 7 inches, illustrated. Bound in morocco. New York: 1923. John Wiley & Sons, Inc.

Kent's handbook needs no introduction to the mechanical engineering public. Since the first edition was published in 1895 and throughout the succeeding eight editions, it has been widely used as a practical reference book of engineering data. These editions, however, have largely been revisions of the material in the first edition, with the addition of new material from time to time as the scope of the mechanical engineering field changed and broadened, and the result has been the gradual development of a lack of balance in the material in the book. Some divisions of the science, which 28 years ago held first rank, are now of relatively minor importance, while other divisions have taken their place. To correct this condition, in the present edition the book has been completely rewritten by a large corps of contributors, each chosen for his fitness to select the material for one of the sections. The editor-in-chief, who is the son of the original founder, has followed the latter's fundamental idea that the book be kept one of engineering practice rather than engineering theory. Among the new subjects appearing for the first time in this edition are Aeronautics, Automobiles, Heat Insulation, Reinforced Concrete, Safety Engineering and Machine Design. Many other sections have been rewritten so that they are practically new. The tenth edition contains over 50 percent more matter than the previous edition, and has been carefully edited to insure the greatest practical convenience to the user.

BOILER MAKER'S POCKET BOOK. By Maurice John Sexton. Revised by P. W. Maguire. Seventh edition. Pages, 292. Size 3 by 434 inches. Illustrated. Bound in cloth. London, England: 1923. E. and F. N. Spon, Ltd. New York: Spon and Chamberlain.

The seventh edition of this pocket book contains useful information on boiler making, shipbuilding and the steel and iron trades in general. In preparing the seventh edition it has been the endeavor of the authors to supply such information as has been found necessary to bring the material in line with developments during the last few years. The tables in the front part of the book were compiled by the author for his own personal use and should be found valuable in general shop work. Special attention has been paid to the watertube boiler, general information and descriptions of various types having been included. Superheaters, fuel economizers, chain grate stokers and assisted draft plants have been dealt with; also abstracts from the latest Board of Trade regulations have been given. The book should prove particularly useful to boiler makers, shop foremen, managers and engineers in charge of boiler plants and those interested in the purchase of boilers for commercial use, keeping in mind, however, that the practice is British rather than American and the information should be utilized accordingly.

# TRADE PUBLICATIONS

LIGHTING DATA.—Four bulletins on the use of proper lighting facilities in industry have been compiled by the Department of Publicity, Edison Lamp Works, Harrison, N. J. Two of these on lighting legislation and the lighting of steel mills and foundries will be of special interest to many of our readers.

CHARCOAL IRON BOILER TUBES.—An interesting book prepared by the Parkesburg Iron Company, Parkesburg, Pa., outlining the development of process of manufacturing charcoal iron boiler tubes is now available on request. By means of illustrations and descriptive matter the entire story of tubes from the raw material to the finished product is explained in detail.

AIR HOISTS.—Air hoists, patented and built by the Hanna Engineering Works, Chicago, Ill., are described and illustrated with special emphasis given to special features in catalog No. 14 now being sent out by the company. These hoists are designed to meet every known requirement of industry. They embody the simplest possible mechanism and it is stated are free of unnecessary fittings and features that would add to the difficulty of maintenance. The catalog also contains in tabulated form the capacities, weights, code words and other information on Hanna air hoists.

UNDERFEED STOKERS.—The Westinghouse Electric and Manufacturing Company, Stoker Department, South Philadelphia Works, Philadelphia, Pa., describes in some detail the design of a new model multiple retort underfeed stoker. A prominent feature of the new design is the positive control of the contour of the fuel bed. Another feature is the agitating element mounted across the lower end of the stoker adjacent to the retorts which provides a means for maintaining a minimum loss due to combustible in the refuse. The main structure of the stoker is built with heavy supporting members to assure perfect alinement of the parts as well as easy access to an individual part or any group of parts.

# SELECTED BOILER PATENTS

Compiled by GEORGE A. HUTCHINSON, Patent Attorney, Washington Loan and Trust Building Washington, D. C.

Readers wishing copies of patent papers, or any further information regarding any patent described, should correspond with Mr. Hutchinson.

1,440,322. GAGE FOR BOILER TUBES. JOSEPH BENJAMIN WEEKS, OF NORTH SYDNEY, NOVA SCOTIA, CANADA.

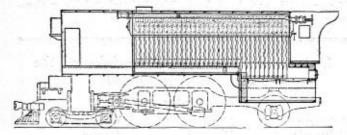

Claim 1.-The herein described apparatus comprising a tapered body portion having a handle formed at one end thereof, a shoulder formed upon

said body portion, a sleeve surrounding said shoulder, a lever pivoted to said body, and a gripping device at one end of said lever for engaging a boiler tube. Five claims.

1,463,494. STEAM CLEANING DEVICE FOR LOCOMOTIVE BOIL-ERS OR THE LIKE. JOHAN BORE AND ALBERT SKOGLUND, OF GOTTENBORG, SWEDEN, ASSIGNORS TO CARL AXEL ARVID WESTERBERG, OF STOCKHOLM, SWEDEN.

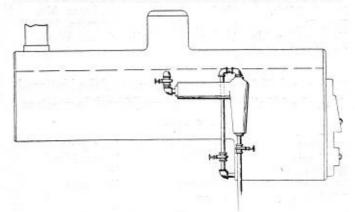

Claim 1.--A locomotive boiler, having a cab at its rear end, a furnace having a side wall, a set of boiler tubes extending lengthwise from the furnace, a tubular nipple extended through the wall with its axis extending

across the axes of the tubes and a steam discharge pipe slidably and rotatably arranged within the nipple, said pipe having a nozzle, and means operable from the cab for turning the nozzle and sliding it transversely of the axis of the tubes for directing the steam into all of said tubes from said nozzle. Eight claims.

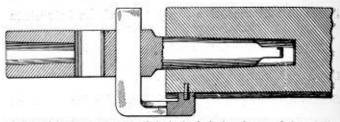

1,459,997. BOILER CLEANER. HARGUS G. SHELLY, OF MUL-VANE, KANSAS.

Claim 1.-A boiler cleaner comprising a horizontally disposed elongated vessel having an inlet connection at one end, the other end of said vessel terminating in a dome shaped enlargement, said enlargement having an out-

let connection, a depending sediment collecting well forming a continuation of said vessel and said enlargement, said enlargement and said well having downwardly tapering walls, a series of vertical, radially disposed perforated baffle plates in said well and a series of vertical, transversely disposed baffle plates in said horizontally disposed vessel. Two claims. 1,442,234. TOOL HOLDER. FRANK H. PETERSEN, OF DENVER, COLORADO, ASSIGNOR, BY MESNE ASSIGNMENTS, OF ONE-HALF TO A. L. WESTON, OF DENVER, COLORADO.

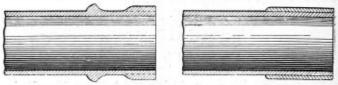

Claim 1.-In apparatus of the class described, the combination with a spindle, means for centering a member thereto, a member centered on the

spindle and having a transverse hole in its body in advance of the spindle end, and means for preventing relative rotation between said member and spindle, said means comprising a dog having a body fitting in said transverse hole. Eight claims.

1.442.458. SUPERHEATER PIPE CONNECTION AND METHOD OF MAKING THE SAME. DAVID H. WILSON, OF WORTENDYKE, NEW JERSEY, AND JAMES E. FULLER, OF FREDONIA, NEW YORK: E. PAULINE WILSON, ADMINISTRATRIX OF SAID DAVID H. WILSON, DECEASED.

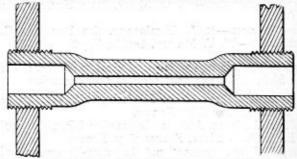

Claim 1.--A superheater tube having a cylindrical inner surface throughout its length, provided upon its outer surface with an upset annular

shoulder, said shoulder being formed upon the outside of said tube from an additional supply of metal stock. Seven claims,

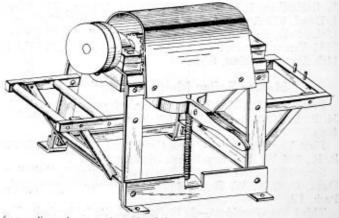

1,466,686. STAY BOLT. WILHELM ZWILLING, OF OSNABRUCK, GERMANY.

Claim 1.-Staybolt securing means, comprising in combination, a staybolt having an end provided with external screwthreads and with a longitudinally

extending cylindrical cavity; and a die, having a cylindrical active portion of greater diameter than the diameter of said cavity, adapted to be inserted into said cavity, the die being provided with a flange adapted to engage the edge of the wall of the cavity to limit its movements into the cavity. Four claums.

1,466.317. BOILER-FLUE CLEANER OR SCALER. CARL A. VONDERHEID AND HERBERT L. EDDY, OF OIL HILL, KANSAS. Claim 1.—A boiler flue cleaner comprising a main frame, a rotary cleaner roll provided with a threaded surface, said cleaner roll supported by said frame, bearing rolls for holding a flue in contact with the cleaner roll, rest

frames disposed at opposite ends of the main frame and adapted to support the extremities of a flue interposed between the cleaner and bearing rolls, and said rest frame being mounted to fold within said main frame when the machine is not in use. Three claims.
